Abstract: In this paper we further develop a general theory of metastable states resulting from perturbation of unstable eigenvalues. We apply this theory to many-body Schrödinger operators and to the problem of quasiclassical tunneling.

1. Introduction

Though the notion of quantum resonance is one of the central notions in physics, the mathematical theory of this phenomenon is still in its early stages. Usually, the resonance is defined in terms of poles of the S -matrix or Green's function, bumps in the scattering cross-section, or solutions of the Schrödinger equation with certain boundary conditions at infinity, while its physical picture is that of a metastable state. It is the latter picture that still is very poorly understood and to which our paper aims to make its modest contribution.

We consider in this paper a self-adjoint operator H_0 on a Hilbert-space \mathcal{H} , such that H_0 has a (possibly degenerate) eigenvalue E_0 which is embedded in the continuous spectrum of H_0 . We perturb H_0 by a symmetric operator W such that the operator $H \equiv H_0 + W$ is self-adjoint, and study the Schrödinger evolution governed by H :

$$i\partial_t\psi = H\psi. \quad (1.1)$$

We assume that initial conditions are spectrally localized (with respect to H) in a neighbourhood, Δ , of E_0 :

$$\psi_0 \equiv \psi|_{t=0} \in \text{Ran } E_\Delta(H). \quad (1.2)$$

Here, $E_\Delta(\lambda)$ is the characteristic function of an interval Δ .

* Research on this paper is supported by NSERC under Grant NA7901.

** This work is part of the first author's PhD requirement.

One expects that the eigenvalue E_0 of H_0 is unstable under the perturbation W , for W sufficiently small. Our goal is to understand how this instability manifests itself on the evolution given by (1.1)–(1.2).

An important additional structure we need is given by a self-adjoint operator A on \mathcal{H} , which measures the degree of *localization* of vectors from \mathcal{H} . Namely, vectors in the domain of $\langle A \rangle^\alpha \equiv (1 + |A|^2)^{\alpha/2}$ for α sufficiently large are said to be *well localized*. In other words, by localization of $\psi \in \mathcal{H}$, we mean its localization in the spectral representation of A . An orbit $\psi(t) \in \mathcal{H}$ is called *dispersive*, or *locally decaying*, if $\|\langle A \rangle^{-\alpha} \psi(t)\|_{\mathcal{H}}$ vanishes as $t \rightarrow \infty$. An obvious example of an operator A is the coordinate, x (or more precisely, $|x|$), if \mathcal{H} is an L^2 -space of functions of x . However, sometimes other choices are more convenient, especially the generator of dilation transformations.

Let P be the orthogonal projector of H_0 onto $\text{Null}(H_0 - E_0)$, $\bar{P} = \mathbb{1} - P$, and let \bar{H} be the reduced Hamiltonian $\bar{H} = \bar{P}H\bar{P}$. We measure the smallness of the perturbation W by the parameter $\kappa \equiv \|\langle A \rangle^\alpha WP\|$. We show that ψ can be written in the form

$$\psi(t) = \psi_{res}(t) + \psi_{disp}(t), \tag{1.3}$$

where $\psi_{res}(t) = (\mathbb{1} + \mathcal{O}(\kappa))P\psi(t)$, $\psi_{disp}(t)$ is dispersive, i.e. $\|\langle A \rangle^{-\alpha} \psi_{disp}(t)\|_{\mathcal{H}} \rightarrow 0$ as $t \rightarrow +\infty$, and

$$P\psi(t) = e^{-i\lambda t}P\psi(0) + \mathcal{O}(\kappa^{1-4\beta}(t+1)^{-\beta}), \tag{1.4}$$

for some bounded operator λ satisfying

$$\text{Re } \lambda = E_0P + \mathcal{O}(\kappa) \quad \text{and} \quad \text{Im } \lambda = -\Gamma + \mathcal{O}(\kappa^3), \tag{1.5}$$

where $\Gamma = \pi \langle W\bar{P}\delta(\bar{H} - E_0)\bar{P}W \rangle_P > 0$, and we used the notation $\langle A \rangle_P \equiv PAP \upharpoonright \text{Ran } P$ for an operator A . The delta-function is defined in (A.24).

Equations (1.3)–(1.4) paint the following picture of the resonance behaviour (see Remark 1 of Sect. 2.2 for a technical discussion). A system which is initially localized in a small spectral interval around an unstable eigenvalue radiates energy/probability to infinity, approaches the unstable unperturbed state, stays near it for a period of time of order $1/\Gamma$, but then eventually loses all the probability to infinity. The decay law (1.5) is given by the celebrated Fermi Golden Rule.

We apply the result above to Schrödinger operators and in particular to N -body systems and to the problem of tunneling.

Remarks. 1. Equations (1.3)–(1.5) imply that H has no eigenvalues in the interval Δ , i.e. that the eigenvalue E_0 of H_0 is unstable under the perturbation W , and that no new eigenvalues emerge. If one is interested in this result alone, a stationary approach would give a simpler proof (cf. [AHS, Sig3] which contain results in this direction).

2. The perturbation parameter κ can be small even when W is large. Exactly this happens in the tunneling resonance problem. In this case W is large but localized in a domain in which P is very small. Our result establishes a relation between the tunneling resonances and the Fermi Golden Rule not observed previously.

3. The bounded operator λ describes the *resonances* of H splitting out of the eigenvalue E_0 of H_0 to the order $\mathcal{O}(\kappa^3)$. One can extend the proof of (1.3)–(1.5) in order to detect the resonance behaviour and obtain *resonances to an arbitrary order*. This way, one can replace the condition $\Gamma > 0$ by the condition which essentially states that *the imaginary*

part of the resonance in question does not vanish at some order (see discussions after Eq. (1.11) and in Sect. 3.1).

4. The assumption $\Gamma > 0$ is satisfied generically for one-body Schrödinger operators [AHS]. The same is expected to hold in a much more general context. Under stronger direct assumptions on H this assumption can be essentially removed (see Remark 3 and discussions in Sects. 2.1–2.3 and 3.1).

Strategy. The key tool used in the proof is a linear variant of the Liapunov-Schmidt projection method in the theory of stable and unstable manifolds, or time-dependent variant of the Feshbach method of perturbation theory. Namely we project Eq. (1.1) along the subspaces $\text{Ran } P$ and $\text{Ran } \bar{P}$ to obtain the new equations

$$i\partial_t P\psi = (E_0 + \langle W \rangle_P)P\psi + PW\bar{P}\psi, \tag{1.6}$$

and

$$i\partial_t \bar{P}\psi = \bar{H}\bar{P}\psi + \bar{P}WP\psi. \tag{1.7}$$

We will not use the second equation in an essential way; instead, we remark the following: in order to control $\bar{\psi} \equiv \bar{P}\psi$ uniformly in κ (or W), we would like to use a local decay estimate for $e^{-i\bar{H}t}\bar{\psi}(0)$. The latter however does not hold for arbitrary initial conditions $\bar{\psi}_0 \equiv \bar{\psi}(0)$, but in general only for initial conditions from certain spectral intervals with respect to \bar{H} , see Condition (A5) and Sect. 4. Now, even if ψ_0 is from an appropriate spectral interval for H , the initial condition $\bar{\psi}_0$ may not be so for \bar{H} . To surmount this problem, we observe that since H is very close to $\bar{P}H\bar{P} + PHP$ and since $\psi_0 \in \text{Ran } E_\Delta(H)$, the portion of $\bar{\psi}_0$ orthogonal to $\text{Ran } g_{\Delta'}(\bar{H})$ is very small. Here, Δ' is an interval containing Δ , and $g_{\Delta'}(\lambda)$ is a smoothed out characteristic function of the interval Δ' (in particular, $g_{\Delta'}(\lambda) = 1, \lambda \in \Delta'$). So we can express $\bar{\psi}$ in terms of the state

$$\psi_d \equiv g_{\Delta'}(\bar{H})\bar{\psi} \tag{1.8}$$

and *a.* This ingenious idea was used first by [SW3]. It yields the following representation for $\bar{\psi}$:

$$\bar{\psi} = B'P\psi + (\mathbb{1} + B')\psi_d, \tag{1.9}$$

where $B' = \mathcal{O}(\kappa)$ (i.e. B' is a bounded operator with norm $\|B'\| \leq C\kappa$). Since $\psi = P\psi_0 + \bar{\psi}$, the full solution is of the form (1.3) with $\psi_{res}(t) = BP\psi(t)$ and $\psi_{disp} = B\psi_d$, where $B = \mathbb{1} + B' = \mathbb{1} + \mathcal{O}(\kappa)$.

With Eqs. (1.6) and (1.8)–(1.9) in place, the stage for analysis is set. The component ψ_d satisfies the local decay property uniformly in κ by Assumption (A4) which is verified for a variety of systems. One important step must be made though, before we embark on estimations of $P\psi(t)$ as a solution to Eq. (1.6): we iterate Eqs. (1.6) and (1.7) (or the resulting equation for ψ_d). This is the only place where Eq. (1.7) is used. The iteration is a rather subtle affair and it takes us to the equation

$$i\partial_t P\psi = \lambda P\psi + f, \tag{1.10}$$

where λ is of the form (1.5) and f satisfies the estimate

$$r(t) \equiv -i \int_0^t e^{-i\lambda(t-s)} f(s) ds = \mathcal{O}(\kappa), \quad t \geq 0. \tag{1.11}$$

The purpose of this iteration is to pick up the leading imaginary term in the bounded operator λ multiplying the function $P\psi(t)$. This leading term is of the second order by Assumption (A5). As a result one needs only one iteration. In general, one should iterate until such a term appears (see discussion in Sect. 3.1). In that case the bounded operator λ yields the resonances of H generated by the perturbation of E_0 to a higher order. Equations (1.10)–(1.11) as well as a priori estimates for the dispersive part ψ_d form a foundation of the proof of the result outlined above.

In the analysis above, $\text{Ran } P$ plays the role of a stable manifold, so the function $\psi_{res}(t)$ describes the motion along this manifold and the component $\bar{\psi}$ is expected to decay, at least locally. (This local decay or radiation to infinity differentiates between infinite and finite dimensional dynamical systems.) However, there are two major differences with the standard case. The first one pertains to the peculiarity of the resonance problem: The stable manifold is not really stable. It behaves as a stable manifold for long time intervals – the life time of the resonance in question – but eventually it disintegrates itself. The second difference is due to the fact that our problem is linear. This allows us to seek *a priori* estimates for the dispersive part ψ , rather than to use the equation for it, Eq. (1.7).

History. Since the early days of quantum physics, the resonance phenomena occupied a central place (see e.g. [BW,KP,S,WW], and [LL] for a textbook discussion). The mathematical theory of resonances could probably be traced to the work of V. Weisskopf and E. Wigner [WW]; in its modern form, it was laid down by B. Simon [Sim1] who used the theory of dilation analytic Hamiltonians due to J. Aguilar and J. M. Combes and E. Balslev and J. M. Combes ([AC, BC]). This approach was further developed in [Sim2, Sig1, Hun2, Ger, HeSj, HM]. Details and extensive references can be found in [HiSig]. It requires the potential in question to have some analyticity properties at least in a neighbourhood of infinity. A theory dispensing with the latter condition was initiated in [Ort].

So far the theory developed was a stationary one, despite the fact that the physical picture (but not the physical definitions!) was that of a metastable state. The time-dependent theory was initiated in works of E. Skibsted and W. Hunziker ([Sk1,2, Hu2]), and a space-time and the phase-space-time and variational analysis was given in [GS] and [PF], respectively. A new powerful approach was suggested by A. Soffer and M. Weinstein [SW3], who also obtained a rather detailed space-time description of evolution of metastable (resonance) states in the one-body Schrödinger case and for a Schrödinger particle coupled to a massive quantum field. Our paper generalizes the result of [SW3] to many-body Schrödinger operators (and degenerate eigenvalues). Besides we also treat the case of quasiclassical resonances, not considered in [SW3]. Though our approach follows the same general line as that of [SW3], we had to introduce some essential changes right at the beginning in order to make it applicable to a considerably wider class of systems.

The approach outlined above was introduced in [SW1] (see also [SW2] and [BP]). The latter work was further improved and coached in terms of the stable-unstable manifold theory in [PW]. This approach is in fact what is known in physics as the (Feshbach) projection method (with the projection operator P). It is usually applied to the stationary Schrödinger equation $(H - E)\psi = 0$, while we apply it to the Schrödinger equation $(H - i\partial_t)\psi = 0$. It serves also as a starting point to a renormalization group construction in a recent work [BFS1-3].

Notation. We use the following notation besides the one introduced above: $E_\Delta(\lambda)$ denotes the characteristic function of an interval Δ , so that $E_\Delta(H)$ is the spectral projector of

H corresponding to the interval Δ . The length of Δ is written as $|\Delta|$. A smoothed characteristic function of an open bounded interval $\Delta \subset \mathbb{R}$ is denoted as g_Δ , i.e. $g_\Delta \in C_0^\infty(\Delta_1)$, where Δ_1 is a slightly bigger interval than Δ , and $g_\Delta(\lambda) = 1$ on Δ . We set $\bar{g}_\Delta \equiv 1 - g_\Delta$.

The norm in the Hilbertspace \mathcal{H} is denoted as $\|\cdot\|_{\mathcal{H}}$, and $\langle \cdot, \cdot \rangle$ is its inner product. The expectation value of an operator B in the state ψ is written as $\langle B \rangle_\psi \equiv \langle \psi, B\psi \rangle$. Moreover, $\langle B \rangle_P$ stands for the operator $PBP \upharpoonright \text{Ran } P$ on the space $\text{Ran } P$.

The domain of an (unbounded) operator A on \mathcal{H} is written as $\mathcal{D}(A)$. For $t \in \mathbb{R}$, let $\langle t \rangle \equiv (1 + t^2)^{1/2}$, and $\langle A \rangle \equiv (1 + A^*A)^{1/2}$, where A^* denotes the adjoint. We also let $\text{Re } A = (A + A^*)/2$, and $\text{Im } A = (A - A^*)/2$.

For a self-adjoint operator H , we set $\delta(H - \lambda) = \frac{1}{\pi} \text{Im}(H - \lambda - i0)^{-1}$, and $\text{P.V.}(H - \lambda)^{-1} = \text{Re}(H - \lambda - i0)^{-1}$, where the r.h.s. are assumed to be defined between appropriate Banach spaces.

Let $\mathcal{L}(\mathcal{H})$ be the space of bounded linear operators on \mathcal{H} with the standard norm $\|\cdot\|$. For a family $\{B_s\}$ of operators in $\mathcal{L}(\mathcal{H})$ depending on the parameter $s \geq 0$, we write $B_s = \mathcal{O}(s)$ if $\|B_s\| \leq Cs$, where C is a constant independent of s . For a complex-valued function $f(s)$, $f(s) = \mathcal{O}(s)$ means $|f(s)| \leq Cs$ and for $\phi_s \in \mathcal{H}$, $\phi_s = \mathcal{O}(s)$ means $\|\phi_s\|_{\mathcal{H}} = \mathcal{O}(s)$.

Finally, for notational convenience, C will denote a generic strictly positive constant whose value can vary from expression to expression (C is allowed to depend on $\alpha, \beta, |\Delta|$, see below, but not on κ or t).

2. Main Results

2.1. Assumptions. We will work in the setting presented above, and where $\dim \text{Ran } P \leq \infty$. The operators H_0 and H are assumed to be self-adjoint on the same domain, and W to be symmetric. We also assume that there is a self-adjoint operator A and a number $\alpha > 2$ such that:

- (A1) $\|\langle A \rangle^\alpha P\| < \infty$,
- (A2) the perturbation W satisfies $\kappa \equiv \|\langle A \rangle^\alpha WP\| < \infty$,
- (A3) the multi-commutators $ad_A^{(k)}(H)$ are H -bounded, uniformly in W , $k = 1, \dots, n$, where $n > \alpha + 1$,
- (A4) the following local decay estimate holds for all $\phi \in \mathcal{D}(\langle A \rangle^\alpha)$ and $t \geq 0$:

$$\|\langle A \rangle^{-\alpha} e^{-i\bar{H}t} g_{\Delta'}(\bar{H}) \bar{P}\phi\|_{\mathcal{H}} \leq C \langle t \rangle^{-\alpha} \|\langle A \rangle^\alpha \bar{P}\phi\|_{\mathcal{H}}, \quad (2.1)$$

for some constant $C > 0$ independent of W ,

- (A5) the Fermi Golden Rule condition holds for E_0 in the sense that there is a $C_0 > 0$ such that the bounded, nonnegative operator

$$\Gamma \equiv \pi \langle W\delta(\bar{H} - E_0)\bar{P}W \rangle_P$$

satisfies:

$$\Gamma \geq C_0 \kappa^2. \quad (2.2)$$

Remarks. 1. (A1)–(A3) are easily verified in the applications (see Sect. 2.3).

2. The uniformity clause in (A3) and (A4) is a restriction on the class of W 's allowed for a given H_0 .

3. In Sect. 4, we derive Condition (A4) from the Mourre estimate. It is much easier to check the latter, as we demonstrate in examples below.

4. It is shown in the appendix that Γ is well defined and satisfies $\|\Gamma\| \leq C\kappa^2$ (see the remark after (A.24)). Hence (A5) gives

$$C_0\kappa^2 \leq \|\Gamma\| \leq C\kappa^2. \tag{2.3}$$

5. If the Mourre estimate holds then one can show (see e.g. [Sig2]) that $\Gamma = \gamma\kappa^2 + \mathcal{O}(\kappa^{7/3})$, where $\gamma = \pi \langle U\delta(\bar{H}_0 - E_0)\bar{P}U \rangle_P$, and $U = W/\kappa$.

6. Condition (A5), or its more precise form given in Remark 5, is conjectured to hold generically. For a more detailed discussion in the case of Schrödinger operators see Paragraph 2.3. In fact, Condition (A5) can be removed at the expense of requiring a larger α in Conditions (A1)–(A4) and a lengthier proof (see discussion in Sect. 3.1).

7. The smoothness Condition (A3) can be thought of as a $C^n(\mathbb{R})$ property of the family $H(\theta) = U(\theta)^{-1}HU(\theta)$, where $U(\theta) = \exp(i\theta A)$, the dilation group.

2.2. *Abstract result.* We present our main result in the setting of a general Hilbert-space (in Theorem 2.1). We treat the case of Schrödinger operators in Sect. 2.3.

Theorem 2.1. *Let $\alpha > 2$ and $0 \leq \beta < \min\{1/2, \alpha - 2\}$ and let ψ be the solution of $i\partial_t\psi = H\psi$, with initial condition $\psi_0 \in \text{Ran } E_\Delta(H) \cap \mathcal{D}(\langle A \rangle^\alpha)$. Then there exists a constant κ_0 (depending on α, β and $|\Delta|$) such that for $\kappa < \kappa_0$ we have the expansion:*

$$\psi(t) = (\mathbb{I} + \mathcal{O}(\kappa))P\psi(t) + \psi_{disp}(t), \tag{2.4}$$

where $\psi_{disp}(t)$ is a dispersive wave satisfying for $t \geq 0$:

$$\|\langle A \rangle^{-\alpha} \psi_{disp}(t)\|_{\mathcal{H}} \leq C \left(\|\langle A \rangle^\alpha \bar{P}\psi_0\|_{\mathcal{H}} \langle t \rangle^{-\alpha} + \kappa^{1-2\beta} \langle t \rangle^{-\beta} \right), \tag{2.5}$$

and $P\psi(t)$ satisfies for $t \geq 0$:

$$P\psi(t) = e^{-i\lambda t}P\psi_0 + \mathcal{O}(\kappa^{1-4\beta} \langle t \rangle^{-\beta}). \tag{2.6}$$

Here λ is a bounded linear operator on $\text{Ran } P$ satisfying

$$\text{Re } \lambda = E_0P + PWP - PW \left(\text{P.V.}(\bar{H} - E_0)^{-1} \right) \bar{P}WP + \mathcal{O}(\kappa^3), \tag{2.7}$$

and

$$\text{Im } \lambda = -\Gamma + \mathcal{O}(\kappa^3). \tag{2.8}$$

The terms on the r.h.s. of (2.7) and (2.8) are well defined.

Corollary 2.2. *Under the assumptions of Theorem 2.1, H has no eigenvalues in the interval Δ .*

Remarks. 1. Equations (2.4)–(2.8) imply that though any orbit $\psi(t)$ starting at $\psi_0 \in \text{Ran } E_\Delta(H)$ is dispersive (i.e. locally decaying), for $\|\bar{P}\psi_0\|_{\mathcal{H}}$ small and for any $R > 0$, the state $\chi_{|A| \leq R} \psi(t)$ is close to the “stationary” state $\chi_{|A| \leq R} e^{-i\lambda t}P\psi_0$ in a time interval of the order $\frac{1}{\kappa} \ln(\kappa^{-1})$.

2. Our analysis yields a more detailed information about $P\psi(t)$ and $\psi_{disp}(t)$ than the one given in Theorem 2.1. The dispersive wave satisfies

$$\begin{aligned} \|\langle A \rangle^{-\alpha} \psi_{disp}(t)\|_{\mathcal{H}} &\leq C \|\langle A \rangle^\alpha \bar{P}\psi_0\|_{\mathcal{H}} (\langle t \rangle^{-\alpha} + \langle t \rangle^{-\beta} \kappa^{2-2\beta}) \\ &\quad + C \|P\psi_0\|_{\mathcal{H}} \langle t \rangle^{-\beta} \kappa^{1-2\beta}. \end{aligned}$$

Set $P\psi(t) = e^{-i\lambda t} P\psi(0) + r(t)$. Then we have in particular

$$\|r(t)\|_{\mathcal{H}} \leq C (\|\langle A \rangle^\alpha \bar{P}\psi_0\|_{\mathcal{H}} \kappa^{1-2\beta} + \|P\psi_0\|_{\mathcal{H}} \kappa^{1-4\beta}) \langle t \rangle^{-\beta}. \quad (2.9)$$

3. There are various versions of Theorem 2.1 in which the condition $\psi_0 \in \text{Ran } E_\Delta(H) \cap \mathcal{D}(\langle A \rangle^\alpha)$ is either relaxed or modified (e.g. to $\psi_0 \in \text{Ran } P$).

2.3. *Schrödinger operators.* In this section, we choose our Hilbert-space to be $\mathcal{H} = L^2(X) \equiv L^2$ (with norm $\|\cdot\|_2$), where X is a finite dimensional inner product space, the configuration space of a system in question. The Hamiltonian is given by

$$H_0 = -\Delta + V, \quad (2.10)$$

where Δ is the Laplacian on X , and V is a real function on X called the potential. Our choice of the operator A is the dilation generator

$$A = \frac{1}{2}(x \cdot p + p \cdot x),$$

where $p = -i\nabla$, and the dot product is a coupling of X and X' . We assume here that $W = \kappa'U$, where κ' is a real number, and $U : X \rightarrow \mathbb{R}$, $\dim \text{Ran } P < \infty$. Setting $\kappa \equiv \|\langle A \rangle^\alpha WP\|$ as before, we have $\kappa = \kappa' \|\langle A \rangle^\alpha UP\|$, and $\kappa \rightarrow 0$ is equivalent to $\kappa' \rightarrow 0$, provided $\|\langle A \rangle^\alpha UP\| < \infty$ (see (2.11)). Making the perturbation small means here to make κ' small. We assume that for some $n > \alpha + 1$:

- (S1) $V, U \in C^n$, with bounded derivatives,
- (S2) (i) $(x \cdot \nabla)^k V$ is H -bounded, $0 \leq k \leq n$,
 (ii) $(x \cdot \nabla)^k U$ is H -bounded, $0 \leq k \leq n$,
- (S3) there exists a neighbourhood Δ_1 of E_0 such that

$$E_{\Delta_1}(H_0) i[H_0, A] E_{\Delta_1}(H_0) \geq \theta_1 E_{\Delta_1}(H_0) + K,$$

where $\theta_1 > 0$ and K is a compact operator on L^2 ,

- (S4) the Fermi Golden Rule Condition holds in the sense that

$$\Gamma = \pi(\kappa')^2 \langle U \delta(\bar{H}_0 - E_0) \bar{P}U \rangle_P > 0$$

(Γ is positive definite).

Conditions (S2) with $k = 0, 1$ and (S3) imply that the projection P satisfies the following two estimates:

$$\|\langle A \rangle^\alpha UP\| < \infty, \quad (2.11)$$

and for any multi-indices \mathbf{m}_1 and \mathbf{m}_2 with $|\mathbf{m}_{1,2}| \leq n$:

$$\|x^{\mathbf{m}_1} p^{\mathbf{m}_2} P\| < \infty. \quad (2.12)$$

Indeed, proceeding as in [HS1,CFKS], one can show that there is a $\delta > 0$ such that $\|e^{\delta|x|} P\| < \infty$. Using then $(p^2 + V)P = E_0 P$, and Condition (S1), it is easily shown that $\|e^{\delta|x|} p^{\mathbf{m}} P\| < \infty$, for $|\mathbf{m}| \leq n$, from which (2.11) and (2.12) follow.

Remark. In the one-body case (see e.g. the problem of tunneling in Sect. 2.3.2), Condition (S4) was shown to hold generically at least for E_0 simple ([AHS], for more details see below). The latter is still a conjecture in the many-body case. The only general results in that case are those of [AHS]. Translated into our context they state, under some additional conditions, that $\delta(\overline{H}_0 - E_0) \neq 0$ and that, given a many-body Hamiltonian H_0 as above and an open set $\Omega \subset X$ (for the definition of X see Sect. 2.3.1) there is a real potential $G \in C_0^\infty(\Omega)$, s.t. $\langle G\delta(\overline{H} - E_0)G \rangle_P > 0$ at least for E_0 simple.

Theorem 2.3. *Theorem 2.1 holds for the Schrödinger operator (2.10) if we replace Conditions (A1)–(A5) by (S1)–(S4).*

The proof of Theorem 2.3 is given in Sect. 5. It consists in showing that the Conditions (S) imply the Conditions (A) in the case of Schrödinger operators. The essential part is to show that starting from the Mourre estimate (S3) for H_0 , we get a strong Mourre estimate for the reduced Hamiltonian \overline{H} , see Theorem 4.1, and therefore the local decay estimate (A4) for \overline{H} .

2.3.1. N -body systems. For N -body systems in the physical space \mathbb{R}^d , the configuration space is

$$X = \{x = (x_1, \dots, x_N) \in \mathbb{R}^{dN} \mid \sum m_i x_i = 0\}.$$

Here m_i is the mass of particle i . The Hamiltonian H_0 is a Schrödinger operator (2.10) with V_0 , an N -body potential:

$$V_0(x) = \sum_{i < j} V_{ij}(x_i - x_j),$$

where the two-body potentials $V_{ij} : \mathbb{R}^d \rightarrow \mathbb{R}$ vanish at infinity. In terms of the two-body potentials, (S2)(i) means that $(x \cdot \nabla)^k V_{ij}$ is Δ -bounded, $0 \leq k \leq n$. For example, we can take $(x \cdot \nabla)^k V_{ij}$ to be Kato-potentials on \mathbb{R}^d , $0 \leq k \leq n$. Similarly, (S2)(ii) is satisfied if $(x \cdot \nabla)^k U$ are Kato-potentials on \mathbb{R}^{dN} , for $0 \leq k \leq n$.

If E_0 is separated from the thresholds of H_0 , then E_0 is finitely degenerate, $\dim \text{Ran } P < \infty$ (see [HS1,CFKS]), and the Mourre estimate holds for H_0 and A if Δ_1 is sufficiently small. Thus we obtained

Corollary 2.4. *The conclusion of Theorem 2.1 holds under the assumptions on the potentials mentioned above, provided that E_0 is separated from the thresholds of H_0 , and if the Fermi Golden Rule Condition holds.*

2.3.2. Tunneling in quasiclassical approximation. We consider the following initial value problem on $L^2(\mathbb{R}^d)$:

$$i\hbar \partial_t \psi = H\psi, \tag{2.13}$$

$$\psi|_{t=0} \equiv \psi_0 \in \text{Ran } E_{\hbar\Delta}(H), \tag{2.14}$$

where $\hbar > 0$ is considered to be a small parameter, and Δ is an interval to be specified, lying at the bottom of the continuous spectrum of H , and $\hbar\Delta \equiv \{\hbar E \mid E \in \Delta\}$. Here the Schrödinger operator H is given by

$$H = p^2 + V, \quad p = -i\hbar \nabla, \tag{2.15}$$

and V is a volcano-shaped bounded potential with a local minimum at the origin, defined in the Conditions (T) below. We define a reference potential V_0 , such that

- (i) V_0 is $C^n(\mathbb{R}^d)$, and such that $(x \cdot \nabla)^k V_0$ is bounded, $0 \leq k \leq n$,
- (ii) $V_0(x) = V(x)$ in a neighbourhood \mathcal{N} of the origin, and $\inf_{x \in \mathbb{R}^d \setminus \mathcal{N}} V_0(x) > V(0)$.

We set

$$H_0 = p^2 + V_0, \tag{2.16}$$

and therefore $H = H_0 + W$ with $W = V - V_0$. For \hbar small enough, H_0 has a unique (normalized) ground-state φ_0 with energy E_0 separated from the continuous spectrum of H_0 . Let $A \equiv (x \cdot p + p \cdot x)/(2\hbar)$ and $\kappa \equiv \|\langle A \rangle^\alpha W \varphi_0\|_2$.

We give now conditions on the potential V , and state then the result of this section, Theorem 2.5.

- (T1) $V \geq 0$, $V \in C^n(\mathbb{R}^d)$, and $(x \cdot \nabla)^k V$ is bounded, $0 \leq k \leq n$,
- (T2) V has a non-degenerate local minimum at $x = 0$ and vanishes as $|x| \rightarrow \infty$,
- (T3) there is a $\delta > 0$ such that $\Omega_\delta \equiv \{x \in \mathbb{R}^d | V(x) < V(0) + \delta\}$ has a connected component Ω_δ^{ext} containing ∞ , on which $V(x)$ is *non-trapping*: $\forall x \in \Omega_\delta^{ext}$,

$$2(V(0) - V(x)) - x \cdot \nabla V(x) \geq \theta, \quad \text{for some } \theta > 0, \tag{2.17}$$

- (T4) the Fermi Golden Rule Condition holds: $\Gamma \equiv \pi \langle \delta(\bar{H} - E_0) \rangle_{\bar{P}W\varphi_0}$ satisfies $\Gamma \geq C_0 \hbar^p \kappa^2$, for some $p \geq 0$.

Remarks. 1. By non-degeneracy of the local minimum in (T2), we mean that the Hessian of V at 0 is strictly positive definite.

2. From the harmonic approximation (see e.g. [HiSig], Chapter 11), it follows that $E_0 = V(0) + O(\hbar)$. Hence for small \hbar , Condition (ii) implies that the classically allowed region $\{x \in \mathbb{R}^d | V_0(x) \leq E_0\}$ is compact. This implies that φ_0 is localized in x exponentially around the origin: $\forall \epsilon, \epsilon' > 0, \exists C_{\epsilon, \epsilon'}$ (independent of \hbar) such that

$$\|e^{(1-\epsilon)\rho_{E_0}/\hbar} \varphi_0\|_2 \leq C_{\epsilon, \epsilon'} e^{\epsilon'/\hbar}. \tag{2.18}$$

Here, $\rho_{E_0}(x)$ is the geodesic distance between x and 0, measured in the Agmon metric corresponding to the energy E_0 . The proof of (2.18) is easily obtained e.g. from [HiSig], Theorem 3.4.

3. Since $E_0 = V(0) + O(\hbar)$, then for small \hbar , W is supported in the classically forbidden region $\{x \in \mathbb{R}^d | V_0(x) > E_0\}$. The exponential decay (in x) of φ_0 implies then that $\kappa = \|\langle A \rangle^\alpha W \varphi_0\|_2 = O(e^{-\eta/\hbar})$, for some $\eta > 0$.

Theorem 2.5. *Assume Conditions (T1)–(T4) hold, and let $0 \leq \beta < \min\{\alpha - 2, 1/2\}$. Then there is a $\hbar_0 > 0$ (dependent on $\alpha, \beta, n, |\Delta|, p$) such that for $\hbar < \hbar_0$, the solution to (2.13)–(2.14) has the expansion*

$$\psi(t) = a(t)\varphi_1 + \psi_{disp}(t), \tag{2.19}$$

where $\varphi_1 = \varphi_0 + O(\kappa/\hbar)$, and $\psi_{disp}(t)$ is a dispersive wave satisfying for $t \geq 0$:

$$\begin{aligned} \|\langle A \rangle^{-\alpha} \psi_{disp}(t)\|_2 &= \|\langle A \rangle^\alpha \bar{P}\psi_0\|_2 O(\langle t \rangle^{-\alpha} \hbar^{-q}) \\ &\quad + O(\langle t \rangle^{-\beta} \hbar^{-q} \kappa^{1-2\beta}), \end{aligned} \tag{2.20}$$

with q , a positive integer depending on α, β, n, p . Moreover, $a(t) = \langle \varphi_0, \psi(t) \rangle$ satisfies for $t \geq 0$:

$$a(t) = e^{-i\lambda t/\hbar} a(0) + O(\langle t \rangle^{-\beta} \hbar^{-q} \kappa^{1-4\beta}), \tag{2.21}$$

with

$$\operatorname{Re} \lambda = E_0 + \langle W \rangle_{\varphi_0} - \langle P.V.(\overline{H} - E_0)^{-1} \rangle_{\overline{P}W\varphi_0} + O(\hbar^{-2}\kappa^3), \tag{2.22}$$

$$\operatorname{Im} \lambda = -\pi \langle \delta(\overline{H} - E_0) \rangle_{\overline{P}W\varphi_0} + O(\hbar^{-2}\kappa^3). \tag{2.23}$$

We prove Theorem 2.5 in Sect. 6. A general discussion of the quasiclassical Schrödinger problem and extensive references can be found in [HiSig].

3. Proof of Theorem 2.1

The proof of Theorem 2.1 consists of two main steps. In a first step, we establish differential equations for $P\psi$ and $\psi_d(t)$ (the latter function is defined in (1.8)), write the corresponding integral equations, and bring these equations to a convenient form. We do this in Sect. 3.1. In the second step we use these equations in order to prove the desired estimates on $P\psi(t)$ and $\psi_d(t)$. This is done in Sect. 3.2. Theorem 2.1 is then derived by observing that

$$\psi(t) = B(P\psi(t) + \psi_d(t)), \tag{3.1}$$

where the operator B satisfies $B = \mathbb{1} + \mathcal{O}(\kappa)$.

3.1. Differential equations for $P\psi(t)$ and $\psi_{disp}(t)$. In this section, we establish the coupled differential equations for $P\psi$ and ψ_d and iterate them in a suitable manner. The main result here is Eq. (3.13) together with the set of equations (3.14). Projecting (1.1) onto $\operatorname{Ran} P$ and $\operatorname{Ran} \overline{P}$ yields

$$i\partial_t P\psi = (E_0 + PW P) P\psi + PW \overline{P}\psi, \tag{3.2}$$

$$i\partial_t \overline{P}\psi = \overline{H} \overline{P}\psi + \overline{P}W P\psi. \tag{3.3}$$

Recall that $\psi_d = P_d\psi$, where $P_d = g_{\Delta'}(\overline{H})\overline{P}$. To pass from $\overline{P}\psi$ to ψ_d , we multiply both sides of (3.3) by $g_{\Delta'}(\overline{H})$ and get

$$i\partial_t \psi_d = \overline{H}\psi_d + P_d W P\psi. \tag{3.4}$$

Now we express $\overline{P}\psi$ in (3.2) in terms of $P\psi$ and ψ_d . Notice that $\psi_0 \in \operatorname{Ran} E_{\Delta}(H)$, so that $\psi_0 = g_{\Delta}(H)\psi_0$. Hence $\psi = g_{\Delta}(H)\psi$ and therefore $\overline{P}\psi = \overline{P}g_{\Delta}(H)\psi$. Introducing $\mathbb{1} = g_{\Delta'}(\overline{H}) + \overline{g}_{\Delta'}(\overline{H})$ into the last equation yields

$$\begin{aligned} \overline{P}\psi &= (g_{\Delta'}(\overline{H}) + \overline{g}_{\Delta'}(\overline{H}))\overline{P}g_{\Delta}(H)\psi \\ &= \overline{g}_{\Delta'}(\overline{H})\overline{P}g_{\Delta}(H)\psi + g_{\Delta'}(\overline{H})\overline{P}\psi \\ &= \overline{g}_{\Delta'}(\overline{H})\overline{P}g_{\Delta}(H)\overline{P}\psi + \overline{g}_{\Delta'}(\overline{H})\overline{P}g_{\Delta}(H)P\psi + P_d\psi. \end{aligned}$$

Hence $(\mathbb{1} - \overline{g}_{\Delta'}(\overline{H})\overline{P}g_{\Delta}(H))\overline{P}\psi = \overline{g}_{\Delta'}(\overline{H})\overline{P}g_{\Delta}(H)P\psi + \psi_d$. The following proposition is proven in the appendix:

Proposition 3.1. $\overline{g}_{\Delta'}(\overline{H})\overline{P}g_{\Delta}(H) = \mathcal{O}(\kappa)$ and consequently, for small κ , $B \equiv (\mathbb{1} - \overline{g}_{\Delta'}(\overline{H})\overline{P}g_{\Delta}(H))^{-1}$ exists as a bounded linear operator on \mathcal{H} , and $\|B\| \leq C$ (uniformly in κ for small κ).

We have therefore

$$\bar{P}\psi = B'P\psi + B\psi_d, \tag{3.5}$$

where $B' = B - \mathbb{1}$, and B is defined in Proposition 3.1 above. Remark that $B = \mathbb{1} + \mathcal{O}(\kappa)$, and $B' = \mathcal{O}(\kappa)$. With expression (3.5) for $\bar{P}\psi$, we get

$$\psi(t) = BP\psi(t) + \psi_{disp}(t), \tag{3.6}$$

where we defined

$$\psi_{disp}(t) = B\psi_d(t). \tag{3.7}$$

Equation (3.6) shows that ψ is of the form (2.4).

From (3.2) and (3.5), we have the following equation of motion for $P\psi$:

$$i\partial_t P\psi = \lambda_1 P\psi + PW B\psi_d, \tag{3.8}$$

where λ_1 is a bounded linear operator on $\text{Ran } P$:

$$\lambda_1 = E_0 + PWBP. \tag{3.9}$$

Next, we rewrite Eq. (3.4) in the integral form

$$\psi_d(t) = e^{-i\bar{H}t}\psi_d(0) - i \int_0^t e^{-i\bar{H}(t-s)} P_d W P\psi(s) ds. \tag{3.10}$$

The last term can be transformed as follows: pick $z \in \mathbb{C}^+$ and integrate by parts in the following way:

$$\begin{aligned} & -i \int_0^t e^{-i\bar{H}(t-s)} P_d W P\psi(s) ds \\ &= -i e^{-i\bar{H}t} \int_0^t e^{i(\bar{H}-z)s} e^{izs} P_d W P\psi(s) ds \\ &= -(\bar{H} - z)^{-1} P_d W P\psi(t) + e^{-i\bar{H}t} (\bar{H} - z)^{-1} P_d W P\psi(0) \\ & \quad + \int_0^t e^{-i\bar{H}(t-s)} (\bar{H} - z)^{-1} P_d W [izP\psi(s) + (\partial_s P\psi)(s)] ds. \end{aligned} \tag{3.11}$$

In order to make the last term on the r.h.s. of (3.11) small, we want to take z to the real axis. Such a procedure is justified in the first two statements of the proposition to follow. The third statement of this proposition shows why z must approach the real axis from above for $t > 0$ (the outgoing condition).

Proposition 3.2. For $\omega \in \mathbb{R}$ and $\phi \in \mathcal{H} \cap \mathcal{D}(\langle A \rangle^\alpha)$, we have:

- (i) $\forall t \geq 0 : \langle A \rangle^{-\alpha} e^{-i\bar{H}t} (\bar{H} - \omega - i\epsilon)^{-1} P_d \phi$ converges in \mathcal{H} as $\epsilon \downarrow 0$. The limit is denoted as $\langle A \rangle^{-\alpha} e^{-i\bar{H}t} (\bar{H} - \omega - i0)^{-1} P_d \phi$.
- (ii) The convergence in (i) is uniform in $t \in \mathbb{R}_+$, and therefore $t \mapsto \langle A \rangle^{-\alpha} e^{-i\bar{H}t} (\bar{H} - \omega - i0)^{-1} P_d \phi$ is continuous as a map from \mathbb{R}_+ to \mathcal{H} .
- (iii) $\| \langle A \rangle^{-\alpha} e^{-i\bar{H}t} (\bar{H} - \omega - i0)^{-1} P_d \phi \|_{\mathcal{H}} \leq C(t+1)^{-\alpha+1} \| \langle A \rangle^\alpha \bar{P}\phi \|_{\mathcal{H}}, \forall t \geq 0$.

This proposition is proven in the appendix.

Notice that as $\text{Im } z \rightarrow 0$, the individual terms in (3.11) do not converge in \mathcal{H} . However, setting $\omega = \text{Re } z$, and using our assumption that $\langle A \rangle^\alpha WP$ is a bounded operator (see (A2)) and Proposition 3.2, we get for PWB acting on the second term on the r.h.s. of (3.10):

$$\begin{aligned}
& -i \int_0^t PWBe^{-i\bar{H}(t-s)} P_d WP\psi(s) ds \\
& = -i \int_0^t PWB'e^{-i\bar{H}(t-s)} P_d WP\psi(s) ds \\
& \quad - PW(\bar{H} - \omega - i0)^{-1} P_d WP\psi(t) + PWe^{-i\bar{H}t} (\bar{H} - \omega - i0)^{-1} P_d WP\psi(0) \\
& \quad + i \int_0^t PWe^{-i\bar{H}(t-s)} (\bar{H} - \omega - i0)^{-1} P_d W(\omega - \lambda_1) P\psi(s) ds \\
& \quad - i \int_0^t PWe^{-i\bar{H}(t-s)} (\bar{H} - \omega - i0)^{-1} P_d WPWB\psi_d(s) ds,
\end{aligned} \tag{3.12}$$

where the term $PW(\bar{H} - \omega - i0)^{-1} P_d WP\psi(t)$ and similar ones are well defined. To get the last two terms, we replaced $\partial_t P\psi$ in (3.11) using (3.8). Expression (3.12) contains the term of order two in κ that acts on $P\psi(t)$.

Let us choose $\omega \equiv E_0$, so that $\omega - \lambda_1 = -PWB P = \mathcal{O}(\kappa)$. Using (3.8), (3.10) and (3.12), we get our final version of the equation of motion for $P\psi$:

$$i\partial_t P\psi = \lambda P\psi + f, \tag{3.13}$$

where $\lambda \equiv \lambda_1 - PW(\bar{H} - E_0 - i0)^{-1} P_d WP$, $f = \sum_{j=1}^5 f_j$, and the f_j 's are given by

$$\begin{aligned}
f_1(t) &= PWBe^{-i\bar{H}t} \psi_d(0), \\
f_2(t) &= PWe^{-i\bar{H}t} (\bar{H} - E_0 - i0)^{-1} P_d WP\psi(0), \\
f_3(t) &= -i \int_0^t PWe^{-i\bar{H}(t-s)} (\bar{H} - E_0 - i0)^{-1} P_d WPWB P\psi(s) ds, \\
f_4(t) &= -i \int_0^t PWe^{-i\bar{H}(t-s)} (\bar{H} - E_0 - i0)^{-1} P_d WPWB\psi_d(s) ds, \\
f_5(t) &= -i \int_0^t PWB'e^{-i\bar{H}(t-s)} P_d WP\psi(s) ds.
\end{aligned} \tag{3.14}$$

The expression for λ is analyzed in

Proposition 3.3. *The expansion (2.7)–(2.8) holds for λ .*

The proof is given in the appendix.

Discussion. Our proof is based on estimating Eqs. (3.4) and (3.13) (obtained estimates are then synthesized into the final theorem with the help of Eqs. (3.6)–(3.7)). Equation (3.13) is a one-iteration of Eq. (3.8). This iteration is needed so that the bounded operator λ multiplying the vector function $P\psi$ on the r.h.s. of the equation for $P\psi$ captures the leading non-zero term of the imaginary part of the resonance. In our case, due to Assumption (A5), this term is the second order. That is why we need only one iteration.

For the leading term of the imaginary part of a higher order (one can show that the leading term is always of an even order and positive) one should iterate Eq. (3.13) further ($n - 2$ times for order n). Controlling the resulting terms would require faster time decay of terms like $W\psi_d(t)$ which would result in a higher power α in Conditions (A1)–(A4).

3.2. Estimates of $P\psi(t)$ and $\psi_d(t)$ and proof of Theorem 2.1. In this section, we show the estimates given in Theorem 2.1. Due to $\psi = B(P\psi + \psi_d)$ (see (3.6), (3.7)) and Lemma A.1 of the appendix which proves that

$$\| \langle A \rangle^{-\alpha} B\phi \|_{\mathcal{H}} \leq C \| \langle A \rangle^{-\alpha} \phi \|_{\mathcal{H}}, \quad \forall \phi \in \mathcal{H}, \tag{3.15}$$

and

$$\| \langle A \rangle^{-\alpha} B'\phi \|_{\mathcal{H}} \leq C\kappa \| \langle A \rangle^{-\alpha} \phi \|_{\mathcal{H}}, \quad \forall \phi \in \mathcal{H}, \tag{3.16}$$

it suffices to demonstrate appropriate estimates on $P\psi(t)$ and $\psi_d(t)$. To this end, write the integral equations for $P\psi(t)$ and $\psi_d(t)$ (cf. (3.13) and (3.9)):

$$\begin{aligned} P\psi(t) &= e^{-i\lambda t} P\psi(0) + r(t), \\ \psi_d(t) &= e^{-i\bar{H}t} \psi_d(0) + R(t), \end{aligned}$$

where $r(t) = \sum_{j=1}^5 r_j(t)$, with

$$r_j(t) = -i \int_0^t e^{-i\lambda(t-s)} f_j(s) ds, \tag{3.17}$$

$j = 1, \dots, 5$, and

$$R(t) = -i \int_0^t e^{-i\bar{H}(t-s)} P_d W P\psi(s) ds. \tag{3.18}$$

The strategy (see [SW3]) is the following: for $T > 0$ and some $\beta \geq 0$, introduce the norms

$$[r]_T = \sup_{0 \leq t \leq T} (t+1)^\beta \|r(t)\|_{\mathcal{H}} \tag{3.19}$$

and

$$[R]_T = \sup_{0 \leq t \leq T} (t+1)^\beta \| \langle A \rangle^{-\alpha} R(t) \|_{\mathcal{H}}. \tag{3.20}$$

Using (3.17) and (3.18), we then show that $[r]_T \leq C\kappa^{1-2\beta}$, where the constant is independent of T , κ is sufficiently small and $0 \leq \beta < \min\{1/2, \alpha - 2\}$. Taking $T \rightarrow \infty$ gives us the desired result: $\|r(t)\|_{\mathcal{H}} \leq C\kappa^{1-2\beta}(t+1)^{-\beta}$. The corresponding estimate for $\| \langle A \rangle^{-\alpha} \psi_d(t) \|_{\mathcal{H}}$ is obtained similarly. These estimates and Eqs. (3.6), (3.7) and (3.15) imply the proof of Theorem 2.1.

Ingredients of the estimations.

- The basic tool in the estimations is the local decay Assumption (A4), and its integrated version given in Proposition 3.2(iii).

• In order to estimate $\|e^{-i\lambda t}\|$, we use the expansion for λ given in Proposition 3.3. We have

$$\|e^{-i\lambda t}\| \leq e^{C\kappa^3 t} e^{-C_0\kappa^2 t}. \tag{3.21}$$

In order to prove this inequality, we use the differential inequality

$$\begin{aligned} \frac{d}{dt} \|e^{-i\lambda t} u\|^2 &= \langle e^{-i\lambda t} u, i(\lambda^* - \lambda)e^{-i\lambda t} u \rangle \\ &\leq 2 \sup(\operatorname{Im} \lambda) \|e^{-i\lambda t} u\|^2, \end{aligned}$$

and the initial condition $\|e^{-i\lambda t} u\|_{t=0} = \|u\|$ to obtain that $\|e^{-i\lambda t}\| \leq \|e^{\operatorname{Im} \lambda t}\|$. (The latter inequality can also be derived by taking the norm of the Trotter representation of $e^{-i\lambda t} = \lim_{n \rightarrow \infty} [e^{-i \operatorname{Re} \lambda t/n} e^{\operatorname{Im} \lambda t/n}]^n$.) Using that $\operatorname{Im} \lambda = -\Gamma + \mathcal{O}(\kappa^3)$ and that the spectrum of Γ is bounded below by $C_0\kappa^2$, we arrive at (3.21). Setting $\gamma \equiv C_0\kappa^2/2$, we derive from (3.21) for κ small:

$$\|e^{-i\lambda t}\| \leq e^{-\gamma t}, \quad t \geq 0. \tag{3.22}$$

• We have the following uniform bounds in $t \geq 0$. **a)** For $0 \leq \beta \leq \sigma$:

$$(t+1)^\beta \int_0^t e^{-\gamma(t-s)} (s+1)^{-\sigma} ds \leq C(1 + \gamma^{-1-\beta}) \leq C\kappa^{-2-2\beta}.$$

If $0 \leq \beta \leq \sigma - 1$ and $\sigma > 1$, then the r.h.s. above can be replaced by $C(1 + \gamma^{-\beta}) \leq C\kappa^{-2\beta}$.

b) For $\sigma > 1, 0 \leq \beta \leq \sigma - 1$:

$$(t+1)^\beta \int_0^t (t-s+1)^{-\sigma} (s+1)^{-\beta} ds \leq C.$$

Estimations. We use the above mentioned points and the condition $\alpha - 2 \geq \beta$ to estimate $\|r_j(t)\|_{\mathcal{H}}$, for $j = 1, \dots, 5$.

$$\begin{aligned} \mathbf{1) } \|r_1(t)\|_{\mathcal{H}} &\leq \int_0^t e^{-\gamma(t-s)} \|PWB e^{-i\bar{H}s} \psi_d(0)\|_{\mathcal{H}} ds \\ &\leq C \| \langle A \rangle^\alpha \bar{P} \psi_0 \|_{\mathcal{H}} \kappa \int_0^t e^{-\gamma(t-s)} (s+1)^{-\alpha} ds \\ &\leq C \| \langle A \rangle^\alpha \bar{P} \psi_0 \|_{\mathcal{H}} \kappa^{1-2\beta} (1+t)^{-\beta}, \quad t \geq 0. \end{aligned} \tag{3.23}$$

In the second step, we used (3.15) and the local decay estimate (A4).

$$\begin{aligned} \mathbf{2) } \|r_2(t)\|_{\mathcal{H}} &\leq C \|P\psi_0\|_{\mathcal{H}} \kappa^2 \int_0^t e^{-\gamma(t-s)} (s+1)^{-\alpha+1} ds \\ &\leq C \|P\psi_0\|_{\mathcal{H}} \kappa^{2-2\beta} (t+1)^{-\beta}, \quad t \geq 0. \end{aligned} \tag{3.24}$$

$$\mathbf{3) } \|r_3(t)\|_{\mathcal{H}} \leq C\kappa^3 \int_0^t e^{-\gamma(t-s)} \int_0^s (s-\tau+1)^{-\alpha+1} \|P\psi(\tau)\|_{\mathcal{H}} d\tau ds. \tag{3.25}$$

We split $\|P\psi(\tau)\|_{\mathcal{H}}$ as

$$\begin{aligned} \|P\psi(\tau)\|_{\mathcal{H}} &\leq e^{-\gamma\tau}\|P\psi_0\|_{\mathcal{H}} + \|r(\tau)\|_{\mathcal{H}} \leq e^{-\gamma\tau}\|P\psi_0\|_{\mathcal{H}} + [r]_T(\tau + 1)^{-\beta} \\ &\leq C(\gamma^{-\beta}\|P\psi_0\|_{\mathcal{H}} + [r]_T)(\tau + 1)^{-\beta}, \end{aligned}$$

where we used $(\gamma\tau)^\beta e^{-\gamma\tau} \leq C$, uniformly in $\gamma, \tau \geq 0$. So

$$\begin{aligned} \|r_3(t)\|_{\mathcal{H}} &\leq C\kappa^3 (\kappa^{-2\beta}\|P\psi_0\|_{\mathcal{H}} + [r]_T) \int_0^t e^{-\gamma(t-s)}(s + 1)^{-\beta} ds \\ &\leq C\kappa^{1-2\beta} (\kappa^{-2\beta}\|P\psi_0\|_{\mathcal{H}} + [r]_T) (t + 1)^{-\beta}. \end{aligned} \tag{3.26}$$

$$\mathbf{4)} \quad \|r_4(t)\|_{\mathcal{H}} \leq C\kappa^3 \int_0^t e^{-\gamma(t-s)} \int_0^s (s - \tau + 1)^{-\alpha+1} \|\langle A \rangle^{-\alpha} \psi_d(\tau)\|_{\mathcal{H}} d\tau ds.$$

We decompose the last term in the integral as

$$\begin{aligned} \|\langle A \rangle^{-\alpha} \psi_d(\tau)\|_{\mathcal{H}} &\leq \|\langle A \rangle^{-\alpha} e^{-i\bar{H}\tau} \psi_d(0)\|_{\mathcal{H}} + \|\langle A \rangle^{-\alpha} R(\tau)\|_{\mathcal{H}} \\ &\leq C(\tau + 1)^{-\alpha} \|\langle A \rangle^\alpha \bar{P}\psi_0\|_{\mathcal{H}} + (\tau + 1)^{-\beta} [R]_T. \end{aligned}$$

Using this decomposition in the double-integral, we get

$$\|r_4(t)\|_{\mathcal{H}} \leq C (\|\langle A \rangle^\alpha \bar{P}\psi_0\|_{\mathcal{H}} \kappa^{3-2\beta} + [R]_T \kappa^{1-2\beta}) (t + 1)^{-\beta}. \tag{3.27}$$

$$\begin{aligned} \mathbf{5)} \quad \|r_5(t)\|_{\mathcal{H}} &\leq C\kappa^3 \int_0^t e^{-\gamma(t-s)} \int_0^s (s - \tau + 1)^{-\alpha} \|P\psi(\tau)\|_{\mathcal{H}} d\tau ds \\ &\leq C\kappa^{1-2\beta} (\kappa^{-2\beta}\|P\psi_0\|_{\mathcal{H}} + [r]_T) (t + 1)^{-\beta}. \end{aligned} \tag{3.28}$$

Summing (3.23), (3.24), (3.26), (3.27) and (3.28), we find for $0 \leq t \leq T$:

$$\begin{aligned} (t + 1)^\beta \|r(t)\|_{\mathcal{H}} &\leq C[r]_T \kappa^{1-2\beta} + C[R]_T \kappa^{1-2\beta} \\ &\quad + C\|P\psi_0\|_{\mathcal{H}} \kappa^{1-4\beta} + C\|\langle A \rangle^\alpha \bar{P}\psi_0\|_{\mathcal{H}} \kappa^{1-2\beta}, \end{aligned} \tag{3.29}$$

where the r.h.s. is independent of t . In order to close the estimates, we express $[R]_T$ in terms of $[r]_T$. From (3.18), we get

$$\begin{aligned} \|\langle A \rangle^{-\alpha} R(t)\|_{\mathcal{H}} &\leq C\kappa \int_0^t (t - s + 1)^{-\alpha} \|P\psi(s)\|_{\mathcal{H}} ds \\ &\leq C (\kappa^{1-2\beta}\|P\psi_0\|_{\mathcal{H}} + [r]_T \kappa) (t + 1)^{-\beta}, \end{aligned} \tag{3.30}$$

and thus from (3.20): $[R]_T \leq C\kappa^{1-2\beta}\|P\psi_0\|_{\mathcal{H}} + C\kappa[r]_T$. Taking the supremum over $t \in [0, T]$ in (3.29), and replacing $[R]_T$ in (3.29) by the last estimate, we get

$$[r]_T \leq C[r]_T \kappa^{1-2\beta} + C\|P\psi_0\|_{\mathcal{H}} \kappa^{1-4\beta} + C\|\langle A \rangle^\alpha \bar{P}\psi_0\|_{\mathcal{H}} \kappa^{1-2\beta}. \tag{3.31}$$

We can now isolate $[r]_T$ in this inequality if $\beta < 1/2$, and for κ small enough. We get

$$[r]_T \leq C\|P\psi_0\|_{\mathcal{H}} \kappa^{1-4\beta} + C\|\langle A \rangle^\alpha \bar{P}\psi_0\|_{\mathcal{H}} \kappa^{1-2\beta}. \tag{3.32}$$

The estimate is uniform in T , and taking $T \rightarrow \infty$ yields

$$\|r(t)\|_{\mathcal{H}} \leq C\kappa^{1-4\beta}(t+1)^{-\beta}. \tag{3.33}$$

Similarly, using $[r]_T \leq C\kappa^{1-4\beta}$ in (3.30) gives

$$\| \langle A \rangle^{-\alpha} R(t) \|_{\mathcal{H}} \leq C\kappa^{1-2\beta}(t+1)^{-\beta}. \quad \square \tag{3.34}$$

The estimates given in Remark 2 after Theorem 2.1 are immediate from (3.30) and (3.32).

4. The Mourre Estimate for Reduced Operators and Local Decay

4.1. The Mourre estimate. In this section, we derive the strict Mourre estimate for the operator $\bar{H} \equiv \bar{P}H\bar{P}$ from the Mourre estimate for H_0 and use the former to prove the local decay for the operator \bar{H} . We consider perturbations W of the form $W = \kappa'U$, where U is fixed, and κ' is assumed to be sufficiently small. The main result of this section is related to some results in [AHS]. It is given in the following

Theorem 4.1. *Suppose that AP and $[H_0, A](H_0 + i)^{-1}$ are bounded, and that AWP , $W(H_0 + i)^{-1}$ and $[W, A](H_0 + i)^{-1}$ are $\mathcal{O}(\kappa')$. Moreover, suppose that there is a neighbourhood Δ_1 of $E_0 \neq 0$ such that*

$$E_{\Delta_1}(H_0)i[H_0, A]E_{\Delta_1}(H_0) \geq \theta_1 E_{\Delta_1}(H_0) + K, \tag{4.1}$$

where $\theta_1 > 0$ and K is a compact operator. Then $\forall \epsilon > 0 \exists C(\epsilon) > 0$ such that

$$E_{\Delta_3}(\bar{H})i[\bar{H}, A]E_{\Delta_3}(\bar{H}) \geq (\theta_1 - \epsilon)E_{\Delta_3}(\bar{H}), \tag{4.2}$$

for any neighbourhood Δ_3 of E_0 , $\Delta_3 \subset \Delta_1$, provided $|\Delta_3| \leq C(\epsilon)$, and $\kappa' \leq C(\epsilon)$. In particular, $|\Delta_3|$ is so small that $0 \notin \Delta_3$.

Proof. We divide the proof into two steps. In Step 1, we pass from the Mourre estimate for H_0 to a *strong* Mourre estimate for \bar{H}_0 , in an appropriate interval Δ_2 , $0 \notin \Delta_2 \subset \Delta_1$. This is done by shrinking Δ_2 around E_0 as to make the contribution of the compact operator K arbitrarily small. In the second step, we pass from the strong Mourre estimate for \bar{H}_0 to one for \bar{H} .

Step 1. We show that $\forall \epsilon_1 > 0 \exists C_1(\epsilon_1) > 0$ such that

$$E_{\Delta_2}(\bar{H}_0)i[\bar{H}_0, A]E_{\Delta_2}(\bar{H}_0) \geq (\theta_1 - \epsilon_1)E_{\Delta_2}(\bar{H}_0) \tag{4.3}$$

for any neighbourhood Δ_2 of E_0 such that $\Delta_2 \subset \Delta_1$, and $|\Delta_2| \leq C_1(\epsilon_1)$.

Let Δ_2 be an open set containing E_0 but not 0, and $\Delta_2 \subset \Delta_1$. Applying $\bar{P}E_{\Delta_2}(\bar{H}_0) = E_{\Delta_2}(\bar{H}_0)$ to both sides of Eq. (4.1) and using $E_{\Delta_1}(H_0)\bar{P} = E_{\Delta_1}(\bar{H}_0)\bar{P} = E_{\Delta_1}(\bar{H}_0)$, we obtain

$$E_{\Delta_2}(\bar{H}_0)i[\bar{H}_0, A]E_{\Delta_2}(\bar{H}_0) \geq \theta_1 E_{\Delta_2}(\bar{H}_0) + E_{\Delta_2}(\bar{H}_0)KE_{\Delta_2}(\bar{H}_0), \tag{4.4}$$

where the last term on the r.h.s. can be made arbitrarily small by shrinking Δ_2 around E_0 (\bar{H}_0 has no eigenvalues in a neighbourhood of E_0 if $E_0 \neq 0$, thus $E_{\Delta_2}(\bar{H}_0) \rightarrow 0$ strongly; and K is compact). This shows (4.3).

Step 2. Let now Δ_2 satisfy (4.3). We show that $\forall \epsilon_2 > 0 \exists C_2(\epsilon_2) > 0$ such that

$$E_{\Delta_3}(\bar{H})i[\bar{H}, A]E_{\Delta_3}(\bar{H}) \geq (\theta_1 - \epsilon_1 - \epsilon_2)E_{\Delta_3}(\bar{H}), \tag{4.5}$$

for any neighbourhood Δ_3 of E_0 such that $\bar{\Delta}_3 \subset \Delta_2$, provided $\kappa' \leq C_2(\epsilon_2)$. We have

$$[\bar{H}, A] = [\bar{H}_0, A] + [\bar{W}, A]. \tag{4.6}$$

We claim

$$E_{\Delta_2}(\bar{H})[\bar{W}, A]E_{\Delta_2}(\bar{H}) = \mathcal{O}(\kappa'). \tag{4.7}$$

To prove the last estimate, write

$$[\bar{W}, A] = [W, A] + [PWP, A] - [PW, A] - [WP, A].$$

The last three commutators are $\mathcal{O}(\kappa')$ since $\|AP\| < \infty$ and $\|AWP\| = \mathcal{O}(\kappa')$. The fact that $[W, A](\bar{H} + i)^{-1} = \mathcal{O}(\kappa')$ follows from the assumption $[W, A](H_0 + i)^{-1} = \mathcal{O}(\kappa')$ and $W(H_0 + i)^{-1} = \mathcal{O}(\kappa')$.

Let us now examine $E_{\Delta_3}(\bar{H})i[\bar{H}_0, A]E_{\Delta_3}(\bar{H})$, where Δ_3 is a neighbourhood of E_0 , and $\bar{\Delta}_3 \subset \Delta_2$. Let $h \in C_0^\infty(\Delta_2)$ be such that $h = 1$ on Δ_3 . We have $h(\bar{H}) = h(\bar{H}_0) + \mathcal{I}$, where

$$\mathcal{I} \equiv - \int (\bar{H}_0 - z)^{-1} \bar{W} (\bar{H} - z)^{-1} d\tilde{h}(z),$$

and since $[\bar{H}_0, A](\bar{H}_0 + i)^{-1}$ is bounded, and both \mathcal{I} and $(\bar{H}_0 + i)\mathcal{I}$ are $\mathcal{O}(\kappa')$, we get

$$\begin{aligned} E_{\Delta_3}(\bar{H})i[\bar{H}_0, A]E_{\Delta_3}(\bar{H}) &= E_{\Delta_3}(\bar{H})h(\bar{H})i[\bar{H}_0, A]h(\bar{H})E_{\Delta_3}(\bar{H}) \\ &= E_{\Delta_3}(\bar{H})h(\bar{H}_0)i[\bar{H}_0, A]h(\bar{H}_0)E_{\Delta_3}(\bar{H}) + \mathcal{O}(\kappa'). \end{aligned} \tag{4.8}$$

Using (4.3) and $h^2(\bar{H}_0) = h^2(\bar{H}) + \mathcal{O}(\kappa')$, we estimate the first term on the r.h.s. of (4.8) from below by

$$(\theta_1 - \epsilon_1)E_{\Delta_3}(\bar{H})h^2(\bar{H}_0)E_{\Delta_3}(\bar{H}) = (\theta_1 - \epsilon_1)E_{\Delta_3}(\bar{H}) + \mathcal{O}(\kappa').$$

This together with (4.8) implies

$$E_{\Delta_3}(\bar{H})i[\bar{H}_0, A]E_{\Delta_3}(\bar{H}) \geq (\theta_1 - \epsilon_1)E_{\Delta_3}(\bar{H}) + \mathcal{O}(\kappa'). \tag{4.9}$$

Multiplying (4.6) from both sides by $E_{\Delta_3}(\bar{H})$ and taking into account (4.7) and (4.9) yields the desired result (4.5). \square

4.2. Local decay.

Theorem 4.2. *Suppose (A3) and (4.2) hold, $\|W(H_0+i)^{-1}\| < 1$, and $(H_0+i)^m ad_A^{(r)}(P)(H_0+i)^{-m}$ are bounded for $m = 0, 1$ and $r \leq n$. Then there is an interval $\Delta', E_0 \in \Delta' \subset \Delta_3$ such that the local decay estimate (A4) holds.*

Proof. We verify first that we have the upper bound (uniformly in W):

$$\|ad_A^{(k)}(\bar{H})(\bar{H} + i)^{-1}\| \leq C, \quad k = 1, \dots, n. \tag{4.10}$$

Expanding the multicommutator of order k gives

$$ad_A^{(k)}(\bar{H}) = ad_A^{(k)}(\bar{P}H\bar{P}) = \sum_{r_1+r_2+r_3=k} C_{r_1,r_2,r_3} ad_A^{(r_1)}(\bar{P})ad_A^{(r_2)}(H)ad_A^{(r_3)}(\bar{P}). \tag{4.11}$$

Equation (4.10) follows since all the operators

$$ad_A^{(r_1)}(\bar{P}), ad_A^{(r_2)}(H)(H_0 + i)^{-1}, (H_0 + i)ad_A^{(r_3)}(\bar{P})(H_0 + i)^{-1},$$

and $(H_0 + i)(\bar{H} + i)^{-1}$ are bounded (the last fact follows from $\|W(H_0 + i)^{-1}\| < 1$). Theorem 4.1 together with (4.10) imply, due to a result of [HSS] that

$$\|\langle A \rangle^{-\alpha} e^{-i\bar{H}t} P_d \phi\|_{\mathcal{H}} \leq \text{const.} (t + 1)^{-\alpha} \|\langle A \rangle^{\alpha} \bar{P} \phi\|_{\mathcal{H}}, \quad t \geq 0.$$

The constant depends on \bar{H} (and κ) only through $\|ad_A^{(k)}(\bar{H})(\bar{H} + i)^{-1}\|, k = 1, \dots, n$. \square

5. Proof of Theorem 2.3

- We show (A1), i.e. $\|\langle A \rangle^{\alpha} P\| < \infty$. From $\|\langle A \rangle^{\alpha} P\| \leq C(1 + \|A^{\alpha} P\|)$, we see that it is enough to show that $A^n P$ is bounded, for some integer $n \geq \alpha$. Now

$$A^n = \left(\frac{1}{2}(x \cdot p + p \cdot x)\right)^n = \sum_{k=0}^n c_k (x \cdot p)^k. \tag{5.1}$$

But $(x \cdot p)^k P$ is bounded by (2.12), $k \leq n$: in fact, $(x \cdot p)^k$ is a sum of terms of the form $x^{\mathbf{m}} p^{\mathbf{m}}$, where $\mathbf{m} \equiv (m_1, \dots, m_{\nu})$ are multi-indices with $|\mathbf{m}| \equiv \sum_{j=1}^{\nu} m_j \leq k$, $x^{\mathbf{m}} = x_1^{m_1} \dots x_{\nu}^{m_{\nu}}$, and $p^{\mathbf{m}} = (-i)^{|\mathbf{m}|} \partial_{x_1}^{m_1} \dots \partial_{x_{\nu}}^{m_{\nu}}$, with $\nu = \dim X$.

- (A2) follows directly from $W = \kappa' U$ and (2.11).
- We show that (A3) is satisfied. From

$$ad_A^{(k)}(H) = (-2i)^k p^2 + i^k (x \cdot \nabla)^k V + i^k (x \cdot \nabla)^k W,$$

$W = \kappa' U$ and (S2), it is clear that $ad_A^{(k)}(H)$ is H -bounded, uniformly in κ' .

- We show now the local decay estimate (A4). Equation (2.11) shows that $AWP = \mathcal{O}(\kappa')$, and (S2)(ii) with $k = 0, 1$ gives that $W(H_0 + i)^{-1}$ and $[W, A](H_0 + i)^{-1}$ are $\mathcal{O}(\kappa')$. Boundedness of AP follows from $\|\langle A \rangle^{\alpha} P\| < \infty$, which we have shown above, and $[H_0, A](H_0 + i)^{-1}$ is bounded by (S2)(i) with $k = 1$. This together with (S3) shows that the conditions of Theorem 4.1 are met. Due to Theorem 4.2, it is then enough to check that $(H_0 + i)^m ad_A^{(r)}(P)(H_0 + i)^{-m}$ is bounded for $r \leq n, m = 0, 1$. We do this now.

Let $m = 0$. Clearly $ad_A^{(0)}(P) = P$ is bounded. If $r \geq 1$, then $ad_A^{(r)}(P) = ad_{(x \cdot p)}^{(r)}(P)$. This multi-commutator is a sum of terms of the form $(x \cdot p)^l P (x \cdot p)^m, l + m = r$. It is thus enough to show that $x^l p^l P p^m x^m$ is bounded, $|l| + |\mathbf{m}| \leq r, r \leq n$. This is

guaranteed by (2.12). We conclude that $ad_A^{(r)}(P)$ is bounded (and does not depend on κ').

Let $m = 1$. We write

$$(H_0 + i)ad_A^{(r)}(P)(H_0 + i)^{-1} = ad_A^{(r)}(P) + \left[H_0, ad_A^{(r)}(P) \right] (H_0 + i)^{-1}.$$

For $r = 0$, the commutator is zero. For $r > 0$, the general term in the commutator is of the form

$$H_0(x \cdot p)^l P(x \cdot p)^m - (x \cdot p)^l P(x \cdot p)^m H_0.$$

Because H_0 is p^2 -bounded, it is enough to show that $p^2(x \cdot p)^l P(x \cdot p)^m$ is bounded for any $l, m, l + m \leq n$. This is again ensured by (2.12).

- (A5) follows immediately from (S4). \square

6. Proof of Theorem 2.5

The proof of Theorem 2.5 is analogous to the proof of Theorem 2.1 for a non-degenerate eigenvalue E_0 . In the quasiclassical case however, we must keep track of the parameter \hbar . The delicate point in the proof of Theorem 2.5 is to show local decay. The latter is deduced from the quasiclassical Mourre estimate (cf. [G, Gr, HN]). This estimate is of an independent interest. We begin with it.

6.1. The quasiclassical Mourre estimate.

Theorem 6.1. *Assume the non-trapping Condition (T3). Then $\forall \epsilon > 0$, there is a $C_\epsilon > 0$ and a neighbourhood Δ_1 of E_0/\hbar (with $|\Delta_1|$ independent of \hbar) such that for $\hbar \leq C_\epsilon$, we have*

$$E_{\hbar\Delta_1}(\bar{H}) \frac{i}{\hbar} [\bar{H}, A] E_{\hbar\Delta_1}(\bar{H}) \geq (\theta - \epsilon) E_{\hbar\Delta_1}(\bar{H}). \tag{6.1}$$

Proof. We write $[\bar{H}, A] = \bar{P}[H, A]\bar{P} + \bar{P}H[P, A] + [P, A]H\bar{P}$. Since PA and AP are bounded, and $\bar{P}H\bar{P} = \bar{P}W\bar{P} = \mathcal{O}(\kappa)$, we get $\bar{P}[\bar{H}, A]\bar{P} = \bar{P}[H, A]\bar{P} + \mathcal{O}(\kappa)$. Let Δ_1 be an interval containing E_0/\hbar , and of fixed length as specified in Proposition 6.2(i) below, and such that $0 \notin \hbar\Delta_1$. Then we have $E_{\hbar\Delta_1}(\bar{H}) = E_{\hbar\Delta_1}(\bar{H})\bar{P}$, and hence

$$E_{\hbar\Delta_1}(\bar{H}) \frac{i}{\hbar} [\bar{H}, A] E_{\hbar\Delta_1}(\bar{H}) = E_{\hbar\Delta_1}(\bar{H}) \frac{i}{\hbar} [H, A] E_{\hbar\Delta_1}(\bar{H}) + \mathcal{O}(\kappa). \tag{6.2}$$

Now $\frac{i}{\hbar} [H, A] = 2(H - E_0) + 2(E_0 - V(x)) - x \cdot \nabla V(x)$, so with $E_0 \geq V(0)$, it follows that

$$\begin{aligned} & E_{\hbar\Delta_1}(\bar{H}) \frac{i}{\hbar} [\bar{H}, A] E_{\hbar\Delta_1}(\bar{H}) \\ & \geq E_{\hbar\Delta_1}(\bar{H}) \left(2(V(0) - V(x)) - x \cdot \nabla V(x) \right) E_{\hbar\Delta_1}(\bar{H}) + \mathcal{O}(\hbar). \end{aligned} \tag{6.3}$$

Let \mathcal{N} be a bounded neighbourhood of $0 \in \mathbb{R}^d$ on which $V(x) = V_0(x)$ (see (ii) in Paragraph 2.3.2). Let $\partial\mathcal{N} \equiv \bar{\mathcal{N}} \setminus \overset{\circ}{\mathcal{N}}$ be the boundary of \mathcal{N} . We put $\delta_1 = \min_{x \in \partial\mathcal{N}} (V(x) - V(0))$, and $\delta_2 = \min\{\delta_1, \delta\}/2$, where δ is given in (T3). The sets Ω_δ^{ext} , \mathcal{N} and $\Omega_{\delta_2}^C \equiv \{x \in \mathbb{R}^d | V(x) \geq \delta_2\}$ cover \mathbb{R}^d .

We introduce a C^∞ -decomposition of unity: $1 = \chi_1(x) + \chi_2(x) + \chi_3(x)$, such that $\text{supp}\chi_1 \subset \mathcal{N}$, $\text{supp}\chi_2 \subset \Omega_\delta^{ext}$, $\text{supp}\chi_3 \subset \Omega_{\delta_2}^C$. We estimate the r.h.s. of (6.3) on the supports of χ_1 , χ_2 and χ_3 . We have

$$\chi_3(x)E_{\hbar\Delta_1}(H) = \mathcal{O}(e^{-\rho/\hbar}), \tag{6.4}$$

for some $\rho > 0$ (see [Gr], Lemma 6). On the support of χ_1 we have $V(x) = V_0(x)$, suggesting that $\chi_1 E_{\hbar\Delta_1}(\bar{H})$ is close to $\chi_1 E_{\hbar\Delta_1}(\bar{H}_0)$, which in turn is zero if $\hbar\Delta_1$ does not contain any eigenvalues of \bar{H}_0 . We have in fact

Proposition 6.2. *There is a neighbourhood $\hbar\Delta_1$ of E_0 , such that $|\Delta_1|$ is independent of \hbar ($|\Delta_1|$ depends only on the second derivatives of V at the origin), and such that*

- (i) $\hbar\Delta_1 \cap \sigma(H_0) = \{E_0\}$,
- (ii) $\chi_1 E_{\hbar\Delta_1}(\bar{H}) = \mathcal{O}(\hbar^{1/2})$.

The proof is given below. Putting $1 = \chi_1(x) + \chi_2(x) + \chi_3(x)$ in front of the last factor $E_{\hbar\Delta_1}(\bar{H})$ in the r.h.s. of (6.3), we then get, using (6.4), Proposition 6.2 and the non-trapping Condition (T3):

$$\begin{aligned} & E_{\hbar\Delta_1}(\bar{H}) \frac{i}{\hbar} [\bar{H}, A] E_{\hbar\Delta_1}(\bar{H}) \\ & \geq E_{\hbar\Delta_1}(\bar{H}) (2(V(0) - V(x)) - x \cdot \nabla V(x)) (\chi_1(x) + \chi_2(x)) E_{\hbar\Delta_1}(\bar{H}) + \mathcal{O}(\hbar) \\ & \geq E_{\hbar\Delta_1}(\bar{H}) \left(\theta \chi_2(x) + \mathcal{O}(\hbar^{1/2}) \right) E_{\hbar\Delta_1}(\bar{H}) + \mathcal{O}(\hbar) \\ & \geq E_{\hbar\Delta_1}(\bar{H}) \left(\theta + \mathcal{O}(\hbar^{1/2}) \right) E_{\hbar\Delta_1}(\bar{H}). \quad \square \end{aligned} \tag{6.5}$$

Proof of Proposition 6.2. (i) is a simple consequence of the harmonic approximation.

In order to prove (ii), we introduce the unitary transformation \mathcal{U} on $L^2(\mathbb{R}^d)$ defined by

$$(\mathcal{U}\psi)(x) = \hbar^{d/4} \psi(\hbar^{1/2}x), \quad \psi \in L^2(\mathbb{R}^d). \tag{6.6}$$

It is easily seen that $\mathcal{U}H\mathcal{U}^{-1} = \hbar H'$, $\mathcal{U}H_0\mathcal{U}^{-1} = \hbar H'_0$, where the rescaled Hamiltonians are given by $H' = -\Delta + \hbar^{-1}V(\hbar^{1/2}x)$, and $H'_0 = -\Delta + \hbar^{-1}V_0(\hbar^{1/2}x)$. The spectra are related as $\sigma(H) = \hbar\sigma(H')$, and $\sigma(H_0) = \hbar\sigma(H'_0)$. For a function g of H , we have $\mathcal{U}g(H)\mathcal{U}^{-1} = g(\hbar H')$. We let $\bar{H}' \equiv \bar{P}'H'\bar{P}'$, where $\bar{P}' = \mathbb{1} - P'$, $P' = \mathcal{U}P\mathcal{U}^{-1}$, and $\bar{H}'_0 \equiv \bar{P}'H'_0\bar{P}'$.

Pick now $g \in C_0^\infty$ such that $g = 1$ on Δ_1 , and $\text{supp}g \cap \sigma(H'_0) = \{E_0/\hbar\}$ (this is possible by (i)). Since $g(\bar{H}'_0) = 0$, we have

$$\begin{aligned} \chi_1(\hbar^{1/2}x)g(\bar{H}') &= \chi_1(\hbar^{1/2}x) \left(g(\bar{H}') - g(\bar{H}'_0) \right) \\ &= -\chi_1(\hbar^{1/2}x) \int (\bar{H}'_0 - z)^{-1} \bar{P}' \frac{1}{\hbar} W(\hbar^{1/2}x) \bar{P}' (\bar{H}' - z)^{-1} d\tilde{g} \\ &= -\chi_1(\hbar^{1/2}x) \int (H'_0 - z)^{-1} \frac{1}{\hbar} W(\hbar^{1/2}x) \bar{P}' (\bar{H}' - z)^{-1} d\tilde{g} + \mathcal{O}(\hbar^{-1}\kappa). \end{aligned} \tag{6.7}$$

In the last step, we used

$$P' \frac{1}{\hbar} W(\hbar^{1/2}x) = \frac{1}{\hbar} \mathcal{U}P W \mathcal{U}^{-1} = \mathcal{O}(\hbar^{-1}\kappa). \tag{6.8}$$

The r.h.s. of (6.7) is now shown to be small by commuting $\chi_1(\hbar^{1/2}x)$ through the resolvent $(H'_0 - z)^{-1}$ to the right, and using $\chi_1(\hbar^{1/2}x)W(\hbar^{1/2}x) = 0$:

$$\begin{aligned} & \chi_1(\hbar^{1/2}x)(H'_0 - z)^{-1} \frac{1}{\hbar} W(\hbar^{1/2}x) \\ &= (H'_0 - z)^{-1} \left[-\Delta, \chi_1(\hbar^{1/2}x) \right] (H'_0 - z)^{-1} \frac{1}{\hbar} W(\hbar^{1/2}x) \\ &= -2\hbar^{1/2}(H'_0 - z)^{-1} \nabla \cdot (\nabla \chi_1)(\hbar^{1/2}x)(H'_0 - z)^{-1} \frac{1}{\hbar} W(\hbar^{1/2}x) \\ &\quad + \hbar(H'_0 - z)^{-1} (\Delta \chi_1)(\hbar^{1/2}x)(H'_0 - z)^{-1} \frac{1}{\hbar} W(\hbar^{1/2}x). \end{aligned} \tag{6.9}$$

Notice that $\|(H'_0 - z)^{-1} \nabla\| \leq C |\operatorname{Im} z|^{-1}$, uniformly in \hbar , and that

$$\begin{aligned} (H'_0 - z)^{-1} \frac{1}{\hbar} W(\hbar^{1/2}x) \overline{P'}(\overline{H'} - z)^{-1} &= (\overline{H'_0} - z)^{-1} - (\overline{H'} - z)^{-1} + \mathcal{O}(\hbar^{-1}\kappa) \\ &= \mathcal{O}(|\operatorname{Im} z|^{-1}) + \mathcal{O}(\hbar^{-1}\kappa). \end{aligned}$$

We then get from (6.7) and (6.9):

$$\chi_1(\hbar^{1/2}x)g(\overline{H'}) = \mathcal{O}(\hbar^{1/2}). \tag{6.10}$$

Notice that we were able to use $\int |\operatorname{Im} z|^{-4} d\tilde{y} < C$, uniformly in \hbar , since the size of the support of the function g is independent of \hbar . From (6.10), it follows that

$$\mathcal{U}^{-1} \chi_1(\hbar^{1/2}x)g(\overline{H'})\mathcal{U} = \chi_1 \mathcal{U}^{-1} g(\overline{H'})\mathcal{U} = \chi_1 g(\overline{H}/\hbar) = \mathcal{O}(\hbar^{1/2}), \tag{6.11}$$

and (ii) of Proposition 6.2 is proved by multiplying the last equation by $E_{\hbar\Delta_1}(\overline{H})$. \square

6.2. Local decay in the quasiclassical case.

Theorem 6.3. *Suppose that the Mourre estimate (6.1) holds, and that Conditions (ii) and (T1) of Paragraph 2.3.2 are satisfied. Then there is an interval $\Delta' \subset \Delta_1$ such that the local decay estimate holds:*

$$\| \langle A \rangle^{-\alpha} e^{-i\overline{H}t/\hbar} g_{\hbar\Delta'}(\overline{H}) \overline{P'} \phi \|_2 \leq C \hbar^{-N} \langle t \rangle^{-\alpha} \| \langle A \rangle^\alpha \overline{P'} \phi \|_2, \tag{6.12}$$

where N is an integer depending on α, n , and C depends on $|\Delta'|$, but not on \hbar .

Proof. Via the unitary transformation \mathcal{U} (introduced in the previous paragraph), (6.12) is equivalent to

$$\| \langle A \rangle^{-\alpha} e^{-i\overline{H}'t} g_{\Delta'}(\overline{H}') \overline{P'} \phi \|_2 \leq C \hbar^{-N} \langle t \rangle^{-\alpha} \| \langle A \rangle^\alpha \overline{P'} \phi \|_2. \tag{6.13}$$

Notice that \mathcal{U} commutes with A . From (6.1), we get by conjugating with \mathcal{U} :

$$E_{\Delta_1}(\overline{H}') i[\overline{H}', A] E_{\Delta_1}(\overline{H}') \geq (\theta - \epsilon) E_{\Delta_1}(\overline{H}'). \tag{6.14}$$

We have also

$$\| ad_A^{(k)}(g_{\Delta'}(\overline{H}')) \| \leq C_k \hbar^{-2k}. \tag{6.15}$$

Estimate (6.15) is obtained by using the representation (A.1) and expanding the multicommutator (as in the proof of Lemma A.1, see (A.12)). From (6.14) and (6.15), we get (6.13) following [HSS] and keeping track of the dependence on \hbar in (6.15). \square

6.3. *Proof of Theorem 2.5.* Remarks 2 and 3 after Conditions (T) in Paragraph 2.3.2 show that (A1) and (A2) are satisfied. Clearly, (A3) is also true by (T1) and Condition (i); in fact, $ad_A^{(k)}(H)(H+i)^{-1} = \mathcal{O}(\hbar^k)$. (A4) holds modulo the factor \hbar^{-N} (see Theorem 6.3), and (A5) holds modulo \hbar^p (see (T4)). Theorem 2.5 follows proceeding as in the proof of Theorem 2.1, and keeping track of \hbar . \square

A. Appendix

We first present an operator calculus which we then apply to find some norm-estimates on the operator B introduced in Proposition 3.1 that were used at various places in this work. In the subsequent sections, we give the proofs of Propositions 3.1–3.3.

A.1. Operator calculus. The operator calculus presented below is based on a formula due to Helffer and Sjöstrand [HeSj] with estimates of the remainders given in [IS, HS2] (see also [D]). We follow [HS2]. Let A be a self-adjoint operator. For a complex-valued $g \in C_0^\infty(\mathbb{R})$, we have the representation

$$g(A) = \int (A - z)^{-1} d\tilde{g}(z), \tag{A.1}$$

where the integral is over \mathbb{C} , $\tilde{g}(z)$ is an almost analytic extension of g to the complex plane, and

$$d\tilde{g}(z) \equiv \frac{1}{2\pi} (\partial_x + i\partial_y)\tilde{g}(z) dx dy. \tag{A.2}$$

The function $\tilde{g}(z)$ has compact support, and satisfies the estimate

$$\int |Im(z)|^{-p} d|\tilde{g}|(z) < \infty, \quad p > 0. \tag{A.3}$$

Consequently, the integral (A.1) converges absolutely in norm.

We need also estimates on commutators like $[h(H), f(A)]$, where H, A are self-adjoint operators, $h \in C_0^\infty$ and $f \in C^\infty$. If the multicommutators $ad_A^{(k)}(H)$, $k = 1, \dots, n$ are H -bounded, and f satisfies the condition given below, then we have the following expansion:

$$[h(H), f(A)] = \sum_{k=1}^{n-1} \frac{1}{k!} f^{(k)}(A) ad_A^{(k)}(h(H)) + R_n, \tag{A.4}$$

where

$$R_n = \int (A - z)^{-n} ad_A^{(k)}(h(H))(A - z)^{-1} d\tilde{f}(z).$$

We then have

$$\|R_n\| \leq C_n \|ad_A^{(n)}(h(H))\| \sum_{k=0}^{n+2} \int \langle x \rangle^{k-n-1} |f^{(k)}(x)| dx, \tag{A.5}$$

where $\langle x \rangle \equiv (1 + x^2)^{1/2}$. The condition on f is that the integrals in (A.5) exist. For details, see [HS2].

A.2. *Proof of Proposition 3.1.* We want to show that $\|\bar{g}_{\Delta'}(\bar{H})\bar{P}g_{\Delta}(H)\| < 1$ for small κ , then B is given by the norm-converging Neumann series

$$B = (\mathbb{1} - \bar{g}_{\Delta'}(\bar{H})\bar{P}g_{\Delta}(H))^{-1} = \sum_{n=0}^{\infty} [\bar{g}_{\Delta'}(\bar{H})\bar{P}g_{\Delta}(H)]^n. \tag{A.6}$$

Since $g_{\Delta}(\bar{H})$ commutes with \bar{P} , and $\bar{g}_{\Delta'}g_{\Delta} = 0$, we get $\bar{g}_{\Delta'}(\bar{H})\bar{P}g_{\Delta}(H) = \bar{g}_{\Delta'}(\bar{H})\bar{P}(g_{\Delta}(H) - g_{\Delta}(\bar{H}))$. Using the second resolvent identity gives

$$\begin{aligned} \bar{P}(g_{\Delta}(H) - g_{\Delta}(\bar{H})) &= -\bar{P} \int [(\bar{H} - z)^{-1} - (H - z)^{-1}] d\tilde{g}_{\Delta}(z) \\ &= - \int (\bar{H} - z)^{-1} \bar{P}W P(H - z)^{-1} d\tilde{g}_{\Delta}(z). \end{aligned} \tag{A.7}$$

With $\|WP\| \leq \kappa$, we get

$$\|(\bar{H} - z)^{-1} \bar{P}W P(H - z)^{-1}\| \leq \frac{\kappa}{|\text{Im}(z)|^2}.$$

Now $|\text{Im}(z)|^{-2}$ is integrable with respect to $d|\tilde{g}_{\Delta}(z)|$, see (A.3). The integral in (A.7) is thus bounded by $\kappa C(\Delta)$, where

$$C(\Delta) = \int |\text{Im}(z)|^{-2} d|\tilde{g}_{\Delta}(z)|,$$

and this shows existence of B for $\kappa < 1/C(\Delta)$. Moreover

$$\|B\| \leq \sum_{n=0}^{\infty} \kappa^n C(\Delta)^n = (1 - \kappa C(\Delta))^{-1}.$$

This completes the proof of the proposition. \square

A.3. *Norm estimates on the operator B.*

Lemma A.1. *We have $\forall \phi \in \mathcal{H}$:*

$$\| \langle A \rangle^{-\alpha} B \phi \|_{\mathcal{H}} \leq C \| \langle A \rangle^{-\alpha} \phi \|_{\mathcal{H}}, \tag{A.8}$$

$$\| \langle A \rangle^{-\alpha} B' \phi \|_{\mathcal{H}} \leq C \kappa \| \langle A \rangle^{-\alpha} \phi \|_{\mathcal{H}}, \tag{A.9}$$

where the constants are independent of κ for small κ .

Proof. Due to (A.6) it is enough to show that

$$\| \langle A \rangle^{-\alpha} \bar{g}_{\Delta'}(\bar{H})\bar{P}g_{\Delta}(H) \langle A \rangle^{\alpha} \| \leq C \kappa. \tag{A.10}$$

Due to (A.7) and $\bar{g}_{\Delta'}(H)g_{\Delta}(H) = 0$, in order to show (A.10), it is enough to show

$$\left\| \int \langle A \rangle^{-\alpha} (\bar{H} - z)^{-1} \bar{P}W P(H - z)^{-1} g_{\Delta}(H) \langle A \rangle^{\alpha} d\tilde{g}_{\Delta'}(z) \right\| \leq C \kappa. \tag{A.11}$$

We have $\|WP\| \leq \kappa$. Introduce $\langle A \rangle^{\alpha} \langle A \rangle^{-\alpha}$ between P and $(H - z)^{-1}$ in (A.11) and notice that $P \langle A \rangle^{\alpha}$ is bounded by Condition (A1). The norm of the integrand in (A.11) is then bounded by

$$\begin{aligned} & \kappa |\operatorname{Im}(z)|^{-1} \| \langle A \rangle^{-\alpha} (H - z)^{-1} g_{\Delta}(H) \langle A \rangle^{\alpha} \| \\ & \leq \kappa |\operatorname{Im}(z)|^{-1} (|\operatorname{Im}(z)|^{-1} + \| \langle A \rangle^{-\alpha} [(H - z)^{-1} g_{\Delta}(H), \langle A \rangle^{\alpha}] \|). \end{aligned}$$

To estimate the commutator in the last expression, notice that $\forall z \notin \mathbb{R}, x \in \mathbb{R}, x \mapsto (x - z)^{-1} g_{\Delta}(x) \in C_0^{\infty}(\Delta)$. Hence we can apply expansion (A.4)-(A.5) with $h(x) \equiv (x - z)^{-1} g_{\Delta}(x)$, and $f(x) = \langle x \rangle^{\alpha}$. Estimate (A.5) implies $\|R_n\| \leq C \|ad_A^{(n)}((H - z)^{-1} g_{\Delta}(H))\|$. Now

$$\begin{aligned} & ad_A^{(k)}((H - z)^{-1} g_{\Delta}(H)) \\ & = \int ad_A^{(k)}((H - z)^{-1} (H - \zeta)^{-1}) d\tilde{g}_{\Delta}(\zeta) \\ & = \sum_{r_1+r_2=k} C_{r_1, r_2} \int ad_A^{(r_1)}((H - z)^{-1}) ad_A^{(r_2)}((H - \zeta)^{-1}) d\tilde{g}_{\Delta}(\zeta), \end{aligned}$$

for some numbers C_{r_1, r_2} . Therefore

$$\begin{aligned} & \|ad_A^{(k)}((H - z)^{-1} g_{\Delta}(H))\| \\ & \leq C \sum_{r_1+r_2=k} \|ad_A^{(r_1)}((H - z)^{-1})\| \int \|ad_A^{(r_2)}((H - \zeta)^{-1})\| d|\tilde{g}_{\Delta}(\zeta)| \end{aligned} \tag{A.12}$$

In order to estimate (A.12) further, observe that

$$\|ad_A^{(k)}((H - z)^{-1})\| \leq C \sum_{j=2}^{k+1} |\operatorname{Im}(z)|^{-j} \tag{A.13}$$

uniformly in κ for small κ . The integral in (A.12) is thus bounded by

$$C \int \sum_{j=2}^{k+1} |\operatorname{Im}(\zeta)|^{-j} d|\tilde{g}_{\Delta}(\zeta)| < \infty,$$

uniformly in κ , for small κ . So we get

$$\|ad_A^{(k)}((H - z)^{-1} g_{\Delta}(H))\| \leq C \sum_{j=2}^{k+1} |\operatorname{Im}(z)|^{-j},$$

and hence the l.h.s. of (A.12) is indeed bounded by

$$C\kappa \int (|\operatorname{Im}(z)|^{-2} + |\operatorname{Im}(z)|^{-n-2}) d|\tilde{g}_{\Delta'}(z)| \leq C\kappa, \tag{A.14}$$

uniformly in κ , for small κ . This shows (A.8). (A.9) is then readily obtained from the fact that $B' = \bar{g}_{\Delta'}(\bar{H})\bar{P}g_{\Delta}(H)B$ and (A.10). \square

A.4. Proof of Proposition 3.2. For $\phi \in \mathcal{D}(\langle A \rangle^{\alpha})$, $\epsilon \downarrow 0, t \geq 0$ fixed, we show that

$$\phi_{\epsilon}(t) \equiv \langle A \rangle^{-\alpha} e^{-i\bar{H}t} (\bar{H} - \omega - i\epsilon)^{-1} P_d \phi$$

is a Cauchy-net in \mathcal{H} . We notice that (for $\epsilon > 0$)

$$(\bar{H} - \omega - i\epsilon)^{-1} = i \int_0^\infty e^{-i(\bar{H} - \omega - i\epsilon)s} ds, \tag{A.15}$$

and so we get, using the first resolvent identity:

$$\begin{aligned} & (\bar{H} - \omega - i\epsilon)^{-1} - (\bar{H} - \omega - i\epsilon')^{-1} \\ &= -i(\epsilon - \epsilon') \int_0^\infty e^{-i(\bar{H} - \omega - i\epsilon)s} ds \int_0^\infty e^{-i(\bar{H} - \omega - i\epsilon')\sigma} d\sigma. \end{aligned}$$

Therefore

$$\begin{aligned} & \|\phi_\epsilon(t) - \phi_{\epsilon'}(t)\|_{\mathcal{H}} \\ & \leq |\epsilon - \epsilon'| \int_0^\infty e^{-\epsilon s} \int_0^\infty e^{-\epsilon' \sigma} \|\langle A \rangle^{-\alpha} e^{-i\bar{H}(t+s+\sigma)} P_d \phi\|_{\mathcal{H}} d\sigma ds \\ & \leq |\epsilon - \epsilon'| \int_0^\infty ds \int_{t+s}^\infty d\tau \|\langle A \rangle^{-\alpha} e^{-i\bar{H}\tau} P_d \phi\|_{\mathcal{H}} \\ & \leq |\epsilon - \epsilon'| \int_0^\infty ds \int_s^\infty d\tau (\tau + 1)^{-\alpha} C \|\langle A \rangle^\alpha \phi\|_{\mathcal{H}}, \end{aligned} \tag{A.16}$$

where we used the local decay (2.1). Since $\alpha > 2$, the double integral in (A.16) is finite, so we get

$$\|\phi_\epsilon(t) - \phi_{\epsilon'}(t)\|_{\mathcal{H}} \leq C|\epsilon - \epsilon'| \|\langle A \rangle^\alpha \phi\|_{\mathcal{H}}, \quad \forall t \geq 0,$$

which shows that ϕ_ϵ is a Cauchy-net, and (i) is proved.

To prove (ii), we remark that from (A.16), we have that the limit $\phi_0(t) \equiv \lim_{\epsilon' \downarrow 0} \phi_{\epsilon'}(t)$ exists, and $\phi_\epsilon \rightarrow \phi_0$ uniformly in t . So ϕ_0 is continuous since the $\phi_{\epsilon'}$'s are.

To prove (iii), remark that ($t \geq 0, \epsilon > 0$):

$$e^{-i\bar{H}t}(\bar{H} - \omega - i\epsilon)^{-1} = ie^{-i\omega t} e^{\epsilon t} \int_t^\infty e^{-i(\bar{H} - \omega - i\epsilon)s} ds,$$

so that we get

$$\begin{aligned} & \|\langle A \rangle^{-\alpha} e^{-i\bar{H}t}(\bar{H} - \omega - i\epsilon)^{-1} P_d \phi\|_{\mathcal{H}} \\ & \leq e^{\epsilon t} \int_t^\infty e^{-\epsilon s} \|\langle A \rangle^{-\alpha} e^{-i\bar{H}s} P_d \phi\|_{\mathcal{H}} ds \\ & \leq C \|\langle A \rangle^\alpha \phi\|_{\mathcal{H}} \int_t^\infty (s + 1)^{-\alpha} ds \\ & \leq C(t + 1)^{-\alpha+1} \|\langle A \rangle^\alpha \phi\|_{\mathcal{H}}. \end{aligned}$$

This completes the proof of the proposition. \square

A.5. Proof of Proposition 3.3. The definition of λ is (see the sentence after (3.13))

$$\lambda = E_0 + PWP + PWB'P - PW(\bar{H} - E_0 - i0)^{-1} P_d WP. \tag{A.17}$$

We analyze first $PWB'P$. Since $B' = \bar{g}_{\Delta'}(\bar{H})\bar{P}g_\Delta(H) + \mathcal{O}(\kappa^2)$, we have

$$PWB'P = PW\bar{g}_{\Delta'}(\bar{H})\bar{P}g_\Delta(H)P + \mathcal{O}(\kappa^3). \tag{A.18}$$

Using $\bar{g}_{\Delta'}(\bar{H})g_{\Delta}(\bar{H}) = 0$, we get

$$\begin{aligned} \bar{g}_{\Delta'}(\bar{H})\bar{P}g_{\Delta}(H) &= \bar{g}_{\Delta'}(\bar{H})\bar{P}(g_{\Delta}(H) - g_{\Delta}(\bar{H})) \\ &= -\bar{g}_{\Delta'}(\bar{H})\bar{P} \int (\bar{H} - z)^{-1}WP(H - z)^{-1}d\check{g}_{\Delta}(z). \end{aligned}$$

Since $(H - z)^{-1} = (H_0 - z)^{-1}(\mathbb{1} - W(H - z)^{-1})$ and PW and WP are $\mathcal{O}(\kappa)$, we deduce that

$$\bar{g}_{\Delta'}(\bar{H})\bar{P}g_{\Delta}(H) = -\bar{g}_{\Delta'}(\bar{H})\bar{P} \int (\bar{H} - z)^{-1}(E_0 - z)^{-1}d\check{g}_{\Delta}(z)WP + \mathcal{O}(\kappa^2). \tag{A.19}$$

Now

$$(\bar{H} - z)^{-1}(E_0 - z)^{-1} = -(\bar{H} - E_0)^{-1}((\bar{H} - z)^{-1} - (E_0 - z)^{-1}),$$

and therefore

$$\begin{aligned} \bar{g}_{\Delta'}(\bar{H})\bar{P}g_{\Delta}(H) &= \bar{g}_{\Delta'}(\bar{H})\bar{P}(\bar{H} - E_0)^{-1}(g_{\Delta}(\bar{H}) - g_{\Delta}(E_0))WP + \mathcal{O}(\kappa^2) \\ &= -\bar{g}_{\Delta'}(\bar{H})\bar{P}(\bar{H} - E_0)^{-1}WP + \mathcal{O}(\kappa^2). \end{aligned}$$

Combining this relation with (A.18), we find

$$PWB'P = -PW\bar{g}_{\Delta'}(\bar{H})(\bar{H} - E_0)^{-1}\bar{P}WP + \mathcal{O}(\kappa^3). \tag{A.20}$$

Notice that the term of order two in κ of $PWB'P$ is self-adjoint.

Let us now examine $PW(\bar{H} - E_0 - i0)^{-1}P_dWP$, which will give the non-zero anti-self-adjoint contribution of order two in κ ,

$$\begin{aligned} PW(\bar{H} - E_0 - i0)^{-1}P_dWP &= PW(\bar{H} - E_0 - i0)^{-1}\bar{P}WP - PW\bar{g}_{\Delta'}(\bar{H})(\bar{H} - E_0)^{-1}\bar{P}WP. \end{aligned} \tag{A.21}$$

Observe that the first term on the r.h.s. exists, because of Proposition 3.2 (and the assumption that $\langle A \rangle^\alpha WP$ is bounded). The second term exists since $E_0 \notin \text{supp}(\bar{g}_{\Delta'})$.

Hence it follows from (A.17), (A.20) and (A.21) that

$$\lambda = E_0 + PWP - PW(\bar{H} - E_0 - i0)^{-1}\bar{P}WP + \mathcal{O}(\kappa^3). \tag{A.22}$$

Notice that since $PW(\bar{H} - E_0 - i\epsilon)^{-1}\bar{P}WP$ converges strongly as $\epsilon \downarrow 0$, then so does its adjoint $PW(\bar{H} - E_0 + i\epsilon)^{-1}\bar{P}WP$. The proof is now complete if one observes that the principal value and the delta-function have the representations:

$$\text{P.V.}(\bar{H} - E_0)^{-1} = \frac{1}{2} \lim_{\epsilon \downarrow 0} ((\bar{H} - E_0 - i\epsilon)^{-1} + (\bar{H} - E_0 + i\epsilon)^{-1}) \tag{A.23}$$

and

$$\delta(\bar{H} - E_0) = \frac{1}{2\pi i} \lim_{\epsilon \downarrow 0} ((\bar{H} - E_0 - i\epsilon)^{-1} - (\bar{H} - E_0 + i\epsilon)^{-1}). \quad \square \tag{A.24}$$

Remark. To show $\|\Gamma\| \leq C\kappa^2$ (see (2.3)), notice that $\|PW(\bar{H} - E_0 \pm i0)^{-1}P_dWP\| = \mathcal{O}(\kappa^2)$. This is shown to hold using Proposition 3.2(ii) with $t = 0$, and the assumption $PW \langle A \rangle^\alpha = \mathcal{O}(\kappa)$.

Acknowledgement. The authors are grateful to J. Fröhlich, W. Hunziker, A. Soffer and M. Weinstein for useful discussions and to A. Soffer and M. Weinstein for making their work available to us prior to publication. It is a pleasure to thank the referee for useful remarks.
